Advances in Information Quality and Management (AIQM) Book Series

Siddhartha Bhattacharyya
RCC Institute of Information Technology, India

ISSN:2331-7701
EISSN:2331-771X

MISSION

Acquiring and managing quality information is essential to an organization's success and profitability. Innovation in information technology provides managers, researchers, and practitioners with the tools and techniques needed to create and adapt new policies, strategies, and solutions for information management.

The **Advances in Information Quality and Management (AIQM) Book Series** provides emerging research principals in knowledge society for the advancement of future technological development. This series aims to increase available research publications and emphasize the global response within the discipline and allow for audiences to benefit from the comprehensive collection of this knowledge.

COVERAGE

- Human and Societal Issue
- Knowledge Management
- Decision Support and Group Decision Support Systems
- Electronic Commerce Technologies
- Supply Chain Management
- Business Process Management and Modeling
- Application of IT to Operation
- Emerging Technologies Management
- IT Innovation and Diffusion
- Web Services and Technologies

IGI Global is currently accepting manuscripts for publication within this series. To submit a proposal for a volume in this series, please contact our Acquisition Editors at Acquisitions@igi-global.com or visit: <http://www.igi-global.com/publish/>.

The Advances in Information Quality and Management (AIQM) Book Series (ISSN 2331-7701) is published by IGI Global, 701 E. Chocolate Avenue, Hershey, PA 17033-1240, USA, www.igi-global.com. This series is composed of titles available for purchase individually; each title is edited to be contextually exclusive from any other title within the series. This book is dedicated to the memory of my late father for the love and care that he always displayed for his family, and for teaching me the importance of humanitarianism. Also, to my beautiful wife, Olga, and our handsome sons, Darius and Cyrus, for filling my life with so much love, joy, and happiness.

Sikirda, Yuliya / Flight Academy, National Aviation University, Ukraine	658
Singhania, Udit / Vellore Institute of Technology, India	87
Spallone, Roberta / Politecnico di Torino, Italy.....	1181
Sridhar, Gumpeny R. / Endocrine and Diabetes Centre, Visakhapatnam, India.....	1888
Stergiou, Ioannis / INFOLYSiS P.C., Greece.....	924
Sugiyama, Shigeki / Independent Researcher, Japan.....	177, 1944
Suman, Ugrasen / School of Computer Science and Information Technology, Devi Ahilya University, India	190
Syropoulos, Apostolos / Greek Molecular Computing Group, Greece	155, 493, 1118, 1662
Syropoulos-Harissis, Demetrios Georgios / Greek Molecular Computing Group, Greece	493
Tamzini, Khaled / LaREMFQ Laboratory, IHEC of Sousse, University of Sousse, Tunisia.....	1578
Theodoropoulos, George / INFOLYSiS P.C., Greece.....	924
Tiwari, Sonal / University of Lucknow, India	1066
Tripathy, B. K. / Vellore Institute of Technology, India.....	87
Tzanis, George / Aristotle University of Thessaloniki, Greece.....	1919
Ugwu, Cyprian Ifeanyi / University of Nigeria, Nsukka, Nigeria & University of South Africa, South Africa	1767
Umukoro, Immanuel Ovemeso / Lagos Business School, Pan-Atlantic University, Nigeria	1699
Usuki, Kiminori / Tokyo Metropolitan Mizuho Noge High School, Japan	904
Vaidya, Akshat / Vellore Institute of Technology, India	98
Vargas Jarillo, Cristóbal / Department of Automatic Control, Centre for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico	1271
Vargas-Bernal, Rafael / Instituto Tecnológico Superior de Irapuato, Mexico	1254
Veglis, Andreas / Aristotle University of Thessaloniki, Greece	1140, 1152
Veloso, Bruno / INESC TEC, Portugal & University Portucalense, Portugal.....	675
Véstias, Mário Pereira / INESC-ID, Instituto Superior de Engenharia de Lisboa, Instituto Politécnico de Lisboa, Portugal	12, 245, 257
Vlaj, Damjan / University of Maribor, Slovenia.....	138
Voskoglou, Michael / Graduate Technological Educational Institute of Western Greece, Greece..	315
Walczak, Steven / University of South Florida, USA	1901
Weiss, Andrew Philip / California State University, Northridge, USA.....	1782
Wernicke, Immo H. / German Government (retired), Germany.....	1323
Williams, Idongesit / Aalborg University, Denmark	1436
Wiseman, Yair / Bar-Ilan University, Israel.....	1
Wong, Sam / University College Roosevelt, The Netherlands	1408
Wright, Michelle F. / Pennsylvania State University, USA & Masaryk University, USA	356, 374
Yasuda, Gen'ichi / Nagasaki Institute of Applied Science, Japan.....	42
Yu, Szde / Wichita State University, USA.....	333
Zgank, Andrej / University of Maribor, Slovenia.....	138
Zhizhin, Gennadiy Vladimirovich / Skolkovo, Russia.....	730
Zinyama, Tawanda / University of Zimbabwe, Zimbabwe	1497, 1597

Table of Contents by Category

Acknowledgment	liv
-----------------------------	-----

Preface	xlii
----------------------	------

Volume I

Section 1: Artificial Intelligence

Autonomous Vehicles	1
---------------------------	---

Yair Wiseman, Bar-Ilan University, Israel

Convolutional Neural Network	12
------------------------------------	----

Mário Pereira Véstias, INESC-ID, Instituto Superior de Engenharia de Lisboa, Instituto Politécnico de Lisboa, Portugal

Human-Agent-Robot Teamwork (HART) Over FiWi-Based Tactile Internet Infrastructures.....	27
---	----

Mahfuzulhoq Chowdhury, Institut National de la Recherche Scientifique (INRS), Canada & University of Quebec, Canada

Martin Maier, Institut National de la Recherche Scientifique (INRS), Canada

Embedded Control System Design for Inverted Pendulum Type Mobile Robots Based on High-Level Petri Nets	42
--	----

Gen'ichi Yasuda, Nagasaki Institute of Applied Science, Japan

Semantic and Formal Representation of Cognitive Models for the Metacognitive Architecture CARINA	54
--	----

Alba J. Jerónimo, Universidad de Córdoba, Colombia

María P. Barrera, Universidad de Córdoba, Colombia

Manuel F. Caro, Universidad de Córdoba, Colombia

Adán A. Gómez, Universidad de Córdoba, Colombia

Error Types in Natural Language Processing in Inflectional Languages	73
--	----

Gregor Donaj, University of Maribor, Slovenia

Mirjam Sepesy Maučec, University of Maribor, Slovenia

Text-Based Image Retrieval Using Deep Learning	87
<i>Udit Singhanian, Vellore Institute of Technology, India</i>	
<i>B. K. Tripathy, Vellore Institute of Technology, India</i>	
Dynamic Load Balancing Using Honey Bee Algorithm: Load Balancing.....	98
<i>Sudha S. Senthilkumar, Vellore Institute of Technology, India</i>	
<i>Brindha K., Vellore Institute of Technology, India</i>	
<i>Nitesh Kumar Agrawal, Vellore Institute of Technology, India</i>	
<i>Akshat Vaidya, Vellore Institute of Technology, India</i>	
Unsupervised Automatic Keyphrases Extraction on Italian Datasets.....	107
<i>Isabella Gagliardi, IMATI-CNR, Italy</i>	
<i>Maria Teresa Artese, IMATI-CNR, Italy</i>	
An Intelligent Machine-Driven Perspective to Archaeological Pottery Reassembly	127
<i>Wilson Sakpere, University of Bologna, Italy</i>	
<i>Valentina Gallerani, University of Bologna, Italy</i>	
Acoustic Presence Detection in a Smart Home Environment.....	138
<i>Andrej Zgank, University of Maribor, Slovenia</i>	
<i>Damjan Vlaj, University of Maribor, Slovenia</i>	

Section 2: Computational Science

Sense and Boundaries of Computer Simulations.....	155
<i>Georgios O. Papadopoulos, National and Kapodistrian University of Athens, Greece</i>	
<i>Apostolos Syropoulos, Greek Molecular Computing Group, Greece</i>	
A General-Purpose Uniform Random Number Package	164
<i>E. Jack Chen, BASF Corporation, USA</i>	
Individual Cloud: After Cloud.....	177
<i>Shigeki Sugiyama, Independent Researcher, Japan</i>	
A Collaborative Ranking Approach for Discovery and Selection of Cloud Services	190
<i>Maya Rathore, Department of Computer Science, Christian Eminent College, Indore, India</i>	
<i>Ugrasen Suman, School of Computer Science and Information Technology, Devi Ahilya University, India</i>	
Tuning Drone Data Delivery and Analysis on the Public Cloud.....	207
<i>Jose Lo Huang, Simon Bolivar University, Venezuela</i>	
Improving the Integration of Distributed Applications	217
<i>José Carlos Martins Delgado, Instituto Superior Técnico, Universidade de Lisboa, Portugal</i>	

A Survey of Tasks Scheduling Algorithms in Distributed Computing Systems	233
<i>Nutan Kumari Chauhan, KIET Group of Institutions, India</i>	
<i>Harendra Kumar, Gurukula Kangri Vishwavidyalaya, India</i>	
High-Speed Viterbi Decoder.....	245
<i>Mário Pereira Véstias, INESC-ID, Instituto Superior de Engenharia de Lisboa, Instituto</i>	
<i>Politécnico de Lisboa, Portugal</i>	
Field-Programmable Gate Array.....	257
<i>Mário Pereira Véstias, INESC-ID, Instituto Superior de Engenharia de Lisboa, Instituto</i>	
<i>Politécnico de Lisboa, Portugal</i>	
Design of a Simple and Low-Cost Calculator in the Laboratory Using FPGA.....	271
<i>Debapriya Mukherjee, University of Calcutta, India</i>	
<i>Kaustav Das, University of Calcutta, India</i>	
<i>Arpita Das, University of Calcutta, India</i>	
Modeling of Uncertain Nonlinear System With Z-Numbers.....	290
<i>Raheleh Jafari, School of Design, University of Leeds, Leeds, UK</i>	
<i>Sina Razvarz, Department of Automatic Control, Centre for Research and Advanced Studies</i>	
<i>of the National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico</i>	
<i>Alexander Gegov, School of Computing, University of Portsmouth, UK</i>	
<i>Satyam Paul, Department of Engineering Design and Mathematics, University of the West of</i>	
<i>England, Bristol, UK</i>	
Use of Grey Numbers for Evaluating a System's Performance Under Fuzzy Conditions.....	315
<i>Michael Voskoglou, Graduate Technological Educational Institute of Western Greece,</i>	
<i>Greece</i>	

Section 3: Cyber Crime, Cyber Bullying, and Digital Terrorism

Cyber Profiling in Criminal Investigation.....	333
<i>Szde Yu, Wichita State University, USA</i>	
Boko Haram's Feminization, Minorization, and Cyberization of Terrorism: Offering the	
Cyberterrorism Diffusion Model as Anti-Bokoharamism Tool.....	344
<i>Adamkolo Mohammed Ibrahim, University of Maiduguri, Nigeria</i>	
Cyberbullying: Definition, Behaviors, Correlates, and Adjustment Problems	356
<i>Michelle F. Wright, Pennsylvania State University, USA & Masaryk University, USA</i>	
What Is Cyberbullying?	374
<i>Michelle F. Wright, Pennsylvania State University, USA & Masaryk University, USA</i>	

How Theoretical Frameworks Inform the Understanding of the Relationship Between Gender and Cyberbullying	387
<i>Monica Bixby Radu, Southeast Missouri State University, USA</i>	
<i>Alexandria L. Rook, Southeast Missouri State University, USA</i>	
The Human Rights-Based Approach to Combat Cyberbullying Against Women and Girls	398
<i>Sabrina Ching Yuen Luk, Nanyang Technological University, Singapore</i>	

Section 4: Cyber Security and Data Protection

Hexa-Dimension Metric, Ethical Matrix, and Cybersecurity	411
<i>Wanbil William Lee, The Computer Ethics Society, Hong Kong & Wanbil and Associates, Hong Kong</i>	
A Utility Theory of Privacy and Information Sharing	428
<i>Julia Puaschunder, The New School, USA</i>	
The 2018 Facebook Data Controversy and Technological Alienation	449
<i>Ananda Mitra, Wake Forest University, USA</i>	
<i>Yasmine Khosrowshahi, Wake Forest University, USA</i>	
Forensic Acquisition Methods for Cloud Computing Environments	462
<i>Diane Barrett, Bloomsburg University of Pennsylvania, USA</i>	
Threats and Vulnerabilities of Mobile Applications	473
<i>Thangavel M., Thiagarajar College of Engineering, India</i>	
<i>Divyaprabha M., Thiagarajar College of Engineering, India</i>	
<i>Abinaya C., Thiagarajar College of Engineering, India</i>	
Web Authorization Protocols	493
<i>Demetrios Georgios Syropoulos-Harissis, Greek Molecular Computing Group, Greece</i>	
<i>Apostolos Syropoulos, Greek Molecular Computing Group, Greece</i>	
Secure and Reliable Knowledge-Based Intrusion Detection Using Mobile Base Stations in Smart Environments	500
<i>Ambika N., Department of Computer Applications, SSMRV College, Bangalore, India</i>	
Improved Cross-Layer Detection and Prevention of Sinkhole Attack in WSN	514
<i>Ambika N., Department of Computer Application, SSMRV College, Bangalore, India</i>	
TDSJ-IoT: Trivial Data Transmission to Sustain Energy From Reactive Jamming Attack in IoT	528
<i>Ambika N., Department of Computer Application, SSMRV College, Bangalore, India</i>	

Section 5: Data Management, Analysis, and Statistics

Software Component Technology: Concepts, Design, and Management Method	542
<i>Fadoua Rehioui, University Soultan Moulay Slimane, Morocco</i>	
An Introduction to Clustering Algorithms in Big Data	559
<i>Rajit Nair, Jagran Lakecity University, India</i>	
<i>Amit Bhagat, Maulana Azad National Institute of India, India</i>	
Challenges in Big Data Analysis	577
<i>M. Govindarajan, Annamalai University, India</i>	
Big Data Analytics and IoT in Smart City Applications.....	586
<i>Mamata Rath, Birla School of Management, Birla Global University, India</i>	
Data Streaming Processing Window Joined With Graphics Processing Units (GPUs).....	602
<i>Shen Lu, University of South Florida, USA</i>	
<i>Richard S. Segall, Arkansas State University, USA</i>	
Statistical Techniques for Research.....	624
<i>Jose Carlos Casas-Rosal, Universidad de Córdoba, Spain</i>	
<i>Carmen León-Mantero, Universidad de Córdoba, Spain</i>	
<i>Noelia Jiménez-Fanjul, Universidad de Córdoba, Spain</i>	
<i>Alexander Maz-Machado, Universidad de Córdoba, Spain</i>	

Volume II

Panel Data: A Case Study Analysis	637
<i>Vera Costa, FEUP, University of Porto, Portugal</i>	
<i>Rui Portocarrero Sarmento, Statsframe, University of Porto, Portugal</i>	
Applications of Decision Support Systems in Aviation.....	658
<i>Tetiana Shmelova, National Aviation University, Ukraine</i>	
<i>Yuliya Sikirda, Flight Academy, National Aviation University, Ukraine</i>	
Classification and Recommendation With Data Streams	675
<i>Bruno Veloso, INESC TEC, Portugal & University Portucalense, Portugal</i>	
<i>João Gama, INESC TEC, Portugal & FEP, University of Porto, Portugal</i>	
<i>Benedita Malheiro, Polytechnic Institute of Porto, Portugal & INESC TEC, Portugal</i>	
N-Tuple Algebra as a Generalized Theory of Relations	685
<i>Boris A. Kulik, Institute for Problems in Mechanical Engineering of RAS, Russia</i>	
<i>Alexander Y. Fridman, Institute for Informatics and Mathematical Modeling of RAS, Russia</i>	
Intelligent Constructing Exact Tolerance Limits for Prediction of Future Outcomes Under Parametric Uncertainty	701
<i>Nicholas Nechval, University of Latvia, Latvia</i>	

The Structure of DNA Taking Into Account the Higher Dimension of Its Components	730
<i>Gennadiy Vladimirovich Zhizhin, Skolkovo, Russia</i>	

Section 6: Data Mining and Databases

Methods and Techniques of Data Mining	749
<i>Ana Funes, Universidad Nacional de San Luis, Argentina</i>	
<i>Aristides Dasso, Universidad Nacional de San Luis, Argentina</i>	
Big Data Mining Algorithms	768
<i>M. Govindarajan, Annamalai University, India</i>	
Graph Database Management Systems: The Past, the Present, and the Future	778
<i>Kornelije Rabuzin, Faculty of Organization and Informatics, University of Zagreb, Croatia</i>	
<i>Martina Šestak, Faculty of Organization and Informatics, University of Zagreb, Croatia</i>	
New Trends in Databases to NonSQL Databases	791
<i>Antonio Sarasa-Cabezuelo, Facultad de Informática, Universidad Complutense de Madrid, Spain</i>	
EDRC: An Early Data Lending-Based Real-Time Commit Protocol	800
<i>Sarvesh Pandey, MMM University of Technology, India</i>	
<i>Udai Shanker, MMM University of Technology, India</i>	
Application of Data Mining in Smart Grid Technology	815
<i>Lipi Chhaya, Researcher, University of Petroleum and Energy Studies, India</i>	
<i>Paawan Sharma, Pandit Deendayal Petroleum University, India</i>	
<i>Adesh Kumar, University of Petroleum and Energy Studies, India</i>	
<i>Govind Bhagwatikar, Sany Wind Energy India Private Limited, India</i>	
N-Clustering of Text Documents Using Graph Mining Techniques	828
<i>Bapuji Rao, Indira Gandhi Institute of Technology, Sarang, India</i>	
Characterization of Elevated Tumor Markers in Diagnosis of HCC Using Data Mining Methods ...	847
<i>Vyshali J. Gogi, Rashtreeya Vidyalaya College of Engineering, India</i>	
<i>Vijayalakshmi M. N., Rashtreeya Vidyalaya College of Engineering, India</i>	
Designing a Concept-Mining Model for the Extraction of Medical Information in Spanish	856
<i>Olga Acosta, Singulartya SpA, Chile</i>	
<i>César Aguilar, Pontificia Universidad Católica de Chile, Chile</i>	

Section 7: Digital and Wireless Communications

Overview of Machine Translation Development	874
<i>Irene Rivera-Trigueros, Department of Translation and Interpreting, University of Granada, Spain</i>	
<i>María-Dolores Olvera-Lobo, Department of Information and Communication Sciences, University of Granada, Spain</i>	
<i>Juncal Gutiérrez-Artacho, Department of Translation and Interpreting, University of Granada, Spain</i>	
Migrating Software Towards Mobile Technologies.....	887
<i>Liliana Maria Favre, Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina & Comisión de Investigaciones Científicas de la Provincia de Buenos Aires, Argentina</i>	
Interaction Speed as Nonverbal Cues in Text Messaging via Smartphone.....	904
<i>Kiminori Usuki, Tokyo Metropolitan Mizuho Noge High School, Japan</i>	
<i>Shogo Kato, Tokyo Woman's Christian University, Japan</i>	
<i>Yuuki Kato, Sagami Women's University, Japan</i>	
Narrowband Internet of Things.....	913
<i>Sudhir K. Routray, Bule Hora University, Bule Hora, Ethiopia</i>	
Interoperability Provision of IoT Data Protocols on Top of Virtualized Infrastructure.....	924
<i>Vaios Koumaras, INFOLYSiS P.C., Greece</i>	
<i>Marianna Kapari, INFOLYSiS P.C., Greece</i>	
<i>Angeliki Papaioannou, INFOLYSiS P.C., Greece</i>	
<i>George Theodoropoulos, INFOLYSiS P.C., Greece</i>	
<i>Ioannis Stergiou, INFOLYSiS P.C., Greece</i>	
<i>Christos Sakkas, INFOLYSiS P.C., Greece</i>	
<i>Harilaos Koumaras, NCSR "Demokritos", Greece</i>	
Network Science for Communication Engineering	939
<i>Sudhir K. Routray, Bule Hora University, Bule Hora, Ethiopia</i>	
Application of Biogeography-Based Optimization to Antennas and Wireless Communications	950
<i>Sotirios K. Goudos, Aristotle University of Thessaloniki, Greece</i>	
Bits'-Carrying Capacities of Switched Local Area Networks	967
<i>Monday Ofori Eyinagho, Afe Babalola University, Nigeria</i>	
<i>Samuel Oluwale Falaki, Afe Babalola University, Nigeria</i>	
Design and Analysis of AWG and FDL-Based Optical Switch in Data Centre Network.....	980
<i>Vaibhav Shukla, Tech Mahindra, Mumbai, India</i>	
<i>Dilip Kumar Choubey, Vellore Institute of Technology, Vellore, India</i>	

Formal Verification of ZigBee-Based Routing Protocol for Smart Grids	1002
<i>Adnan Rashid, National University of Sciences and Technology, Pakistan</i>	
<i>Osman Hasan, National University of Sciences and Technology, Pakistan</i>	
QoS Provisioning for Multicast Routing and Channel Assignment in Wireless Mesh Network.....	1018
<i>Abira Banik, Tripura University, India</i>	
<i>Abhishek Majumder, Tripura University, India</i>	
Evaluating the Effectiveness of Multi-Web Services in Load Balancing Cluster-Based Web Server	1037
<i>Abhijit Bora, Gauhati University, India</i>	
<i>Tulshi Bezboruah, Gauhati University, India</i>	
Challenges and Opportunities of VLC Application in Intelligent Transportation Systems	1051
<i>Aleksandra Kostic-Ljubisavljevic, University of Belgrade, Serbia</i>	
<i>Branka Mikavica, Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia</i>	

Section 8: Digital Media

Antecedents and Consequences of the Growing Popularity of Digital Consumption	1066
<i>Ritu Narang, University of Lucknow, India</i>	
<i>Sonal Tiwari, University of Lucknow, India</i>	
Television Use and Consumption of Elderly Americans	1085
<i>Robert Andrew Dunn, East Tennessee State University, USA</i>	
<i>Stephen W. Marshall, East Tennessee State University, USA</i>	
Social Media and Social Movements: Strengths, Challenges, and Implications for the Future	1096
<i>Sheldondra J. Brown, Southeast Missouri State University, USA</i>	
<i>Grace M. Babcock, North Carolina State University, USA</i>	
<i>Monica Bixby Radu, Southeast Missouri State University, USA</i>	
Digital Social Networks From a Social Capital Perspective.....	1106
<i>Suparna Dhar, NSHM Knowledge Campus, Kolkata, India</i>	
<i>Indranil Bose, Indian Institute of Management, Kolkata, India</i>	
<i>Mohammed Naved Khan, Aligarh Muslim University, India</i>	
Digital Documents	1118
<i>Anastasios Dimou, Independent Researcher, Athens, Greece</i>	
<i>Apostolos Syropoulos, Greek Molecular Computing Group, Greece</i>	
Digital Media and New Forms of Journalism.....	1130
<i>Lambrini Papadopoulou, Aristotle University of Thessaloniki, Greece</i>	
<i>Theodora A. Maniou, University of Cyprus, Cyprus</i>	

Data Journalism: Definition, Skills, Difficulties, and Perspectives.....	1140
<i>Andreas Veglis, Aristotle University of Thessaloniki, Greece</i>	
<i>Charalampos Bratsas, Aristotle University of Thessaloniki, Greece</i>	

Exploring the Integration of User-Generated Content in Media Organizations Through Participatory Journalism	1152
<i>Theodora A. Saridou, Aristotle University of Thessaloniki, Greece</i>	
<i>Andreas Veglis, Aristotle University of Thessaloniki, Greece</i>	

Section 9: Engineering Science and Technologies

Adapting a Requirements Engineering Process by Key Factors Estimation.....	1165
<i>Graciela Dora Susana Hadad, Universidad Nacional del Oeste, Argentina & Universidad de Belgrano, Argentina</i>	
<i>Jorge Horacio Doorn, Universidad Nacional de La Matanza, Argentina & Universidad Nacional de Tres de Febrero, Argentina</i>	
<i>Viviana Alejandra Ledesma, Universidad Nacional de La Matanza, Argentina</i>	

Digital Tools Aimed to Represent Urban Survey	1181
<i>Cristina Boido, Politecnico di Torino, Italy</i>	
<i>Pia Davico, Politecnico di Torino, Italy</i>	
<i>Roberta Spallone, Politecnico di Torino, Italy</i>	

Addressing the New Pragmatic Methods in Urban Design Discipline	1196
<i>Hisham Abusaada, Housing and Building National Research Center (HBRC), Egypt</i>	
<i>Abeer Elshater, Ain Shams University, Egypt</i>	

Reengineering Legacy Systems Towards New Technologies.....	1214
<i>Djelloul Bouchiha, Center University of Naama, Algeria & EEDIS Lab. UDL-SBA, Algeria</i>	

A Comprehensive Update and Performance Evaluation of Friction Factor Formulae	1231
<i>Salihu Lukman, University of Hafr Al-Batin, Saudi Arabia</i>	
<i>Isaiah Adesola Oke, Obafemi Awolowo University, Nigeria</i>	
<i>Afolabi M. Asani, Ladoke Akintola University, Nigeria</i>	

The Role of Two-Dimensional Materials in Electromagnetic Interference Shielding.....	1254
<i>Rafael Vargas-Bernal, Instituto Tecnológico Superior de Irapuato, Mexico</i>	

Effect of Nanoparticle and Inclination Angle at Thermal Efficiency in Heatpipes	1271
<i>Sina Razvarz, Department of Automatic Control, Centre for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico</i>	
<i>Raheleh Jafari, School of Design, University of Leeds, Leeds, UK</i>	
<i>Cristóbal Vargas Jarillo, Department of Automatic Control, Centre for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico</i>	
<i>Alexander Gegov, School of Computing, University of Portsmouth, UK</i>	

Modeling of the Aerodisperse Systems Hydrodynamics in Devices With Directional Motion of the Fluidized Bed	1289
<i>Artem Artyukhov, Sumy State University, Ukraine</i>	
<i>Jan Krmela, Alexander Dubcek University of Trencin, Slovakia</i>	
<i>Nadiia Artyukhova, Sumy State University, Ukraine</i>	
<i>Ruslan Ostroha, Sumy State University, Ukraine</i>	

Volume III

Section 10: Environmental Science and Technologies

Renewable Resources and Value-Based Complex Forest Management	1309
<i>Yuri P. Pavlov, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria</i>	
Agriculture 4.0 and Bioeconomy: Strategies of the European Union and Germany to Promote the Agricultural Sector – Opportunities and Strains of Digitization and the Use of Bio-Based Innovations.....	1323
<i>Immo H. Wernicke, German Government (retired), Germany</i>	
Overview of Solid Waste Management of Healthcare and Related Organisations.....	1336
<i>Isaiah Adesola Oke, Obafemi Awolowo University, Nigeria</i>	
<i>Lukman Salihu, University of Hafr Al-Batin, Saudi Arabia</i>	
<i>Idi Dansuleiman Mohammed, Land, Air, and Water Consulting, Nigeria</i>	
<i>Asani M. Afolabi, Ladoke Akintola University, Nigeria</i>	
Managing Water Resources: Industry Initiative.....	1353
<i>Sabyasachi Nayak, Confederation of Indian Industry, India</i>	
Inhibited Antibiotic-Resistant and Electrochemical Treatment of Pharmaceutical Wastewater	1362
<i>Isaiah Adesola Oke, Obafemi Awolowo University, Nigeria</i>	
<i>Fehintola Ezekiel Oluwaseun, Adeyemi Federal University of Education, Ondo, Nigeria</i>	
<i>Justinah S. Amoko, Adeyemi Federal University of Education, Ondo, Nigeria</i>	
<i>Salihu Lukman, University of Hafr Al-Batin, Saudi Arabia</i>	
<i>Adekunbi Enoch Adedayo, Adeyemi Federal University of Education, Ondo, Nigeria</i>	
Design and Implementation of a Location-Based Service With Emphasis on a Geographical Database.....	1384
<i>Wen-Chen Hu, University of North Dakota, USA</i>	
Climate Change: Inclusion of Gender and Cultural Diversity in Climate Change Actions.....	1398
<i>Mgbeodichinma Eucharia Onuoha Oragwa, Technical University of Mining Bergakadmie Freiberg, Germany</i>	
Gendering Information and Communication Technologies in Climate Change.....	1408
<i>Sam Wong, University College Roosevelt, The Netherlands</i>	

Section 11: Ethics and Responsibility

Science and the Morality of Weapons Research.....	1424
<i>John Forge, University of Sydney, Australia</i>	
Mobilization: Decision Theory	1436
<i>Idongesit Williams, Aalborg University, Denmark</i>	
Moral, Social, and Political Responsibility in the Information Age	1451
<i>Tomas Cahlik, Charles University, Prague, Czech Republic</i>	
The Voice of Social Media, 1997-2018	1461
<i>Bruce Lawrence Cook, Cook Communication, USA</i>	
Breaking Fake News and Verifying Truth	1469
<i>Kazuhiko Shibuya, ROIS, Japan</i>	
Crossfire and Violation of Human Rights in Bangladesh: A Critical Review	1481
<i>Md. Awal Hossain Mollah, University of Rajshahi, Bangladesh</i>	
Politics and Ethics and a National Framework to Combat Corruption in Zimbabwe.....	1497
<i>Tawanda Zinyama, University of Zimbabwe, Zimbabwe</i>	

Section 12: Government, Policy, and Crisis Management

Good Practices in E-Government Accessibility: Lessons From the European Union.....	1513
<i>Fernando Almeida, Polytechnic Institute of Gaya, Portugal</i>	
<i>José Augusto Monteiro, Polytechnic Institute of Gaya, Portugal</i>	
National Systems of Innovation Using an Application on EU Data.....	1526
<i>George M. Korres, University of Aegean, Greece</i>	
<i>Maria P. Michailidis, University of Nicosia, Cyprus</i>	
Comparative Analysis of Applying Behavioral Public Policy to Telecommunication Market by International Organizations.....	1537
<i>Nagayuki Saito, International Professional University of Technology in Tokyo, Japan</i>	
A Good American President	1550
<i>James George, Archway Publishing, USA</i>	
<i>Abdullah Murrar, Indiana University of Pennsylvania, USA</i>	
<i>Pankaj Chaudhary, Indiana University of Pennsylvania, USA</i>	
<i>James Allen Rodger, Indiana University of Pennsylvania, USA</i>	

The Role of DPPs in Promoting Local Government-Citizen Collaboration and Participation: The Case of “Baladiaty”	1578
<i>Khaled Tamzini, LaREMFQ Laboratory, IHEC of Sousse, University of Sousse, Tunisia</i>	
<i>Ynes Hafi, ARSELA, Tunisia</i>	
<i>Achref Ben Ouannes, ARSELA, Tunisia</i>	
<i>Roula Borhani, OMEDRH, Tunis, Tunisia</i>	
Local Government, Decentralisation, Devolution, and Service Delivery in Zimbabwe.....	1597
<i>Tawanda Zinyama, University of Zimbabwe, Zimbabwe</i>	
A Risk Management on Demographic Mobility of Evacuees in Disasters.....	1612
<i>Kazuhiko Shibuya, ROIS, Japan</i>	
GIS-Based Quantitative Landslide Risk Assessment Approach for Property and Life at Bartın Hepler.....	1623
<i>Arzu Erener, Kocaeli University, Turkey</i>	
<i>Gülcan Sarp, Süleyman Demirel University, Turkey</i>	
<i>Şebnem Düzgün, Colorado School of Mines, USA</i>	
Section 13: Human Aspects of Technology	
Technology and the Theory of Apocalypse	1638
<i>Maximiliano Emanuel Korstanje, University of Palermo, Argentina</i>	
Software Literacy as a Vital Digital Literacy in a Software-Saturated World.....	1648
<i>Craig Hight, University of Newcastle, Australia</i>	
<i>Elaine Khoo, The University of Waikato, New Zealand</i>	
ICT Investments on Economic Sectors With International Comparative Advantage and the Diffusion of Prosperity.....	1662
<i>Ioannis Papadopoulos, Metropolitan College, Greece</i>	
<i>Apostolos Syropoulos, Greek Molecular Computing Group, Greece</i>	
Dimensions of the Digital Divide	1672
<i>Marcus Leaning, University of Winchester, UK</i>	
<i>Udo Richard Averweg, eThekweni Municipality, South Africa</i>	
Importance of Digital Literacy and Hindrance Brought About by Digital Divide.....	1683
<i>Mohammad Izzuddin Mohammed Jamil, Universiti Brunei Darussalam, Brunei</i>	
<i>Mohammad Nabil Almunawar, Universiti Brunei Darussalam, Brunei</i>	

Gender Differences in Access to and Use of ICTs in Nigeria.....	1699
<i>Immanuel Ovemeso Umukoro, Lagos Business School, Pan-Atlantic University, Nigeria</i>	
<i>Aanuoluwapo Oluwaseun Omolade-Lawal, University College Hospital, Ibadan, Nigeria</i>	
<i>Samuel Oyelami Babalola, UAC Nigeria Plc, Nigeria</i>	
<i>Kolawole Sunday Akinsumbo, LucrativeTech, Nigeria</i>	
<i>Rashida Mebude Aligwa, Tek Experts Limited, Nigeria</i>	
<i>Balikis Animasaun Abdul-Jeleel, International Institute of Tropical Agriculture (IITA), Nigeria</i>	
How Mobile Technologies Are Leading to Economic Development in Sub-Saharan Africa	1719
<i>Nigel McKelvey, Letterkenny Institute of Technology, Ireland</i>	
<i>Adam Crossan, Letterkenny Institute of Technology, Ireland</i>	
<i>Kevin Curran, Ulster University, UK</i>	

Section 14: Library Science and Research Methods

Informational Competencies	1728
<i>José Poças Rascão, Polytechnic Institute of Setúbal, Portugal</i>	
A Primer on Q-Method and the Study of Technology	1746
<i>Stéphanie Gauttier, Grenoble Ecole de Management, France</i>	
Modernizing the Academic Library.....	1757
<i>Jennifer Ashley Wright Joe, University of Toledo, USA</i>	
Prospects and Challenges of Web 3.0 Technologies Application in the Provision of Library Services.....	1767
<i>Promise Ifeoma Ilo, University Library, Pamo University of Medical Sciences, Port Harcourt, Nigeria</i>	
<i>Christopher Nkiko, Elizade University, Nigeria</i>	
<i>Cyprian Ifeanyi Ugwu, University of Nigeria, Nsukka, Nigeria & University of South Africa, South Africa</i>	
<i>Justina Ngozi Ekere, University of Nigeria, Nsukka, Nigeria</i>	
<i>Roland Izuagbe, Covenant University, Nigeria</i>	
<i>Michael O. Fagbohun, Covenant University, Nigeria</i>	
Massive Digital Libraries (MDLs) and the Impact of Mass-Digitized Book Collections.....	1782
<i>Andrew Philip Weiss, California State University, Northridge, USA</i>	

Section 15: Medical Ethics and Law

Protocol Development in Clinical Trials for Healthcare Management.....	1797
<i>Swati Changdeo Jagdale, School of Pharmacy, Dr. Vishwanath Karad MIT World Peace University, Pune, India</i>	
<i>Asawaree Anand Hable, MAEER's Maharashtra Institute of Pharmacy, Pune, India</i>	
<i>Anuruddha R. Chabukswar, School of Pharmacy, Dr. Vishwanath Karad MIT World Peace University, Pune, India</i>	

A Regulatory and Safety Perspective on Medical Devices	1815
<i>Carla Pires, CBIOS, Universidade Lusófona, Portugal</i>	
<i>Dinah Duarte, CBIOS, Universidade Lusófona, Portugal</i>	
Medical Social Networks, Epidemiology and Health Systems	1827
<i>Patrícia C. T. Gonçalves, INESC TEC, University of Porto, Portugal</i>	
<i>Ana S. Moura, LAQV-REQUIMTE, University of Porto, Portugal</i>	
<i>M. Natália D. S. Cordeiro, LAQV-REQUIMTE, University of Porto, Portugal</i>	
<i>Pedro Campos, INESC TEC, University of Porto, Portugal</i>	
Ambiguities in the Privacy Policies of Common Health and Fitness Apps	1839
<i>Devjani Sen, Algonquin College, Canada</i>	
<i>Rukhsana Ahmed, University at Albany, SUNY, USA</i>	
Generosity in Healthcare Policy Under the Obama Administration: Reflecting Various Dimensions Focused on the ACA	1850
<i>Khadijeh Roya Rouzbehani, University of Victoria, Canada</i>	
Islamic Medical Ethics in Brunei Darussalam Hospitals	1860
<i>Syazana Fauzi, Universiti Brunei Darussalam, Brunei</i>	
Distribution of Selected Health Technology in Regions of Slovakia	1872
<i>Beata Gavurova, Technical University of Košice, Slovakia</i>	
<i>Matus Kubak, Technical University of Kosice, Slovakia</i>	
Section 16: Medical Technologies	
Expanding Scope of Information Technology in Clinical Care	1888
<i>Gumpeny R. Sridhar, Endocrine and Diabetes Centre, Visakhapatnam, India</i>	
Artificial Neural Networks in Medicine: Recent Advances	1901
<i>Steven Walczak, University of South Florida, USA</i>	
Internet of Things and Data Science in Healthcare	1919
<i>George Tzanis, Aristotle University of Thessaloniki, Greece</i>	
<i>Ourania-Ioanna Fotopoulou, Aristotle University of Thessaloniki, Greece</i>	
Internet of Things in Healthcare as an Innovative Form of Personalized Medicine	1933
<i>Ljubica Dikovic, College of Applied Sciences Uzice, Serbia</i>	
Highly Aged and After Cloud	1944
<i>Shigeki Sugiyama, Independent Researcher, Japan</i>	
Gene Editing Technology and Ethical Issues	1952
<i>Barbara Jane Holland, Brooklyn Public Library, USA</i>	
About the Contributors	lvi
Index	xcviii

Table of Contents by Volume

Preface	xlii
----------------------	------

Acknowledgment	liv
-----------------------------	-----

Volume I

Autonomous Vehicles	1
<i>Yair Wiseman, Bar-Ilan University, Israel</i>	

Convolutional Neural Network	12
<i>Mário Pereira Véstias, INESC-ID, Instituto Superior de Engenharia de Lisboa, Instituto Politécnico de Lisboa, Portugal</i>	

Human-Agent-Robot Teamwork (HART) Over FiWi-Based Tactile Internet Infrastructures.....	27
<i>Mahfuzulhoq Chowdhury, Institut National de la Recherche Scientifique (INRS), Canada & University of Quebec, Canada</i>	
<i>Martin Maier, Institut National de la Recherche Scientifique (INRS), Canada</i>	

Embedded Control System Design for Inverted Pendulum Type Mobile Robots Based on High-Level Petri Nets.....	42
<i>Gen'ichi Yasuda, Nagasaki Institute of Applied Science, Japan</i>	

Semantic and Formal Representation of Cognitive Models for the Metacognitive Architecture CARINA	54
<i>Alba J. Jerónimo, Universidad de Córdoba, Colombia</i>	
<i>María P. Barrera, Universidad de Córdoba, Colombia</i>	
<i>Manuel F. Caro, Universidad de Córdoba, Colombia</i>	
<i>Adán A. Gómez, Universidad de Córdoba, Colombia</i>	

Error Types in Natural Language Processing in Inflectional Languages.....	73
<i>Gregor Donaj, University of Maribor, Slovenia</i>	
<i>Mirjam Sepesy Maučec, University of Maribor, Slovenia</i>	

Text-Based Image Retrieval Using Deep Learning	87
<i>Udit Singhania, Vellore Institute of Technology, India</i>	
<i>B. K. Tripathy, Vellore Institute of Technology, India</i>	

Dynamic Load Balancing Using Honey Bee Algorithm: Load Balancing.....	98
<i>Sudha S. Senthilkumar, Vellore Institute of Technology, India</i>	
<i>Brindha K., Vellore Institute of Technology, India</i>	
<i>Nitesh Kumar Agrawal, Vellore Institute of Technology, India</i>	
<i>Akshat Vaidya, Vellore Institute of Technology, India</i>	
Unsupervised Automatic Keyphrases Extraction on Italian Datasets.....	107
<i>Isabella Gagliardi, IMATI-CNR, Italy</i>	
<i>Maria Teresa Artese, IMATI-CNR, Italy</i>	
An Intelligent Machine-Driven Perspective to Archaeological Pottery Reassembly	127
<i>Wilson Sakpere, University of Bologna, Italy</i>	
<i>Valentina Gallerani, University of Bologna, Italy</i>	
Acoustic Presence Detection in a Smart Home Environment.....	138
<i>Andrej Zgank, University of Maribor, Slovenia</i>	
<i>Damjan Vlaj, University of Maribor, Slovenia</i>	
Sense and Boundaries of Computer Simulations.....	155
<i>Georgios O. Papadopoulos, National and Kapodistrian University of Athens, Greece</i>	
<i>Apostolos Syropoulos, Greek Molecular Computing Group, Greece</i>	
A General-Purpose Uniform Random Number Package	164
<i>E. Jack Chen, BASF Corporation, USA</i>	
Individual Cloud: After Cloud	177
<i>Shigeki Sugiyama, Independent Researcher, Japan</i>	
A Collaborative Ranking Approach for Discovery and Selection of Cloud Services	190
<i>Maya Rathore, Department of Computer Science, Christian Eminent College, Indore, India</i>	
<i>Ugrasen Suman, School of Computer Science and Information Technology, Devi Ahilya University, India</i>	
Tuning Drone Data Delivery and Analysis on the Public Cloud	207
<i>Jose Lo Huang, Simon Bolivar University, Venezuela</i>	
Improving the Integration of Distributed Applications	217
<i>José Carlos Martins Delgado, Instituto Superior Técnico, Universidade de Lisboa, Portugal</i>	
A Survey of Tasks Scheduling Algorithms in Distributed Computing Systems	233
<i>Nutan Kumari Chauhan, KIET Group of Institutions, India</i>	
<i>Harendra Kumar, Gurukula Kangri Vishwavidyalaya, India</i>	
High-Speed Viterbi Decoder.....	245
<i>Mário Pereira Véstias, INESC-ID, Instituto Superior de Engenharia de Lisboa, Instituto Politécnico de Lisboa, Portugal</i>	

Field-Programmable Gate Array.....	257
<i>Mário Pereira Véstias, INESC-ID, Instituto Superior de Engenharia de Lisboa, Instituto Politécnico de Lisboa, Portugal</i>	
Design of a Simple and Low-Cost Calculator in the Laboratory Using FPGA.....	271
<i>Debapriya Mukherjee, University of Calcutta, India</i>	
<i>Kaustav Das, University of Calcutta, India</i>	
<i>Arpita Das, University of Calcutta, India</i>	
Modeling of Uncertain Nonlinear System With Z-Numbers.....	290
<i>Raheleh Jafari, School of Design, University of Leeds, Leeds, UK</i>	
<i>Sina Razvarz, Department of Automatic Control, Centre for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico</i>	
<i>Alexander Gegov, School of Computing, University of Portsmouth, UK</i>	
<i>Satyam Paul, Department of Engineering Design and Mathematics, University of the West of England, Bristol, UK</i>	
Use of Grey Numbers for Evaluating a System's Performance Under Fuzzy Conditions.....	315
<i>Michael Voskoglou, Graduate Technological Educational Institute of Western Greece, Greece</i>	
Cyber Profiling in Criminal Investigation.....	333
<i>Szde Yu, Wichita State University, USA</i>	
Boko Haram's Feminization, Minorization, and Cyberization of Terrorism: Offering the Cyberterrorism Diffusion Model as Anti-Bokoharamism Tool.....	344
<i>Adamkolo Mohammed Ibrahim, University of Maiduguri, Nigeria</i>	
Cyberbullying: Definition, Behaviors, Correlates, and Adjustment Problems	356
<i>Michelle F. Wright, Pennsylvania State University, USA & Masaryk University, USA</i>	
What Is Cyberbullying?	374
<i>Michelle F. Wright, Pennsylvania State University, USA & Masaryk University, USA</i>	
How Theoretical Frameworks Inform the Understanding of the Relationship Between Gender and Cyberbullying	387
<i>Monica Bixby Radu, Southeast Missouri State University, USA</i>	
<i>Alexandria L. Rook, Southeast Missouri State University, USA</i>	
The Human Rights-Based Approach to Combat Cyberbullying Against Women and Girls	398
<i>Sabrina Ching Yuen Luk, Nanyang Technological University, Singapore</i>	
Hexa-Dimension Metric, Ethical Matrix, and Cybersecurity	411
<i>Wanbil William Lee, The Computer Ethics Society, Hong Kong & Wanbil and Associates, Hong Kong</i>	

A Utility Theory of Privacy and Information Sharing.....	428
<i>Julia Puauschunder, The New School, USA</i>	
The 2018 Facebook Data Controversy and Technological Alienation	449
<i>Ananda Mitra, Wake Forest University, USA</i>	
<i>Yasmine Khosrowshahi, Wake Forest University, USA</i>	
Forensic Acquisition Methods for Cloud Computing Environments.....	462
<i>Diane Barrett, Bloomsburg University of Pennsylvania, USA</i>	
Threats and Vulnerabilities of Mobile Applications.....	473
<i>Thangavel M., Thiagarajar College of Engineering, India</i>	
<i>Divyaprabha M., Thiagarajar College of Engineering, India</i>	
<i>Abinaya C., Thiagarajar College of Engineering, India</i>	
Web Authorization Protocols.....	493
<i>Demetrios Georgios Syropoulos-Harissis, Greek Molecular Computing Group, Greece</i>	
<i>Apostolos Syropoulos, Greek Molecular Computing Group, Greece</i>	
Secure and Reliable Knowledge-Based Intrusion Detection Using Mobile Base Stations in Smart Environments	500
<i>Ambika N., Department of Computer Applications, SSMRV College, Bangalore, India</i>	
Improved Cross-Layer Detection and Prevention of Sinkhole Attack in WSN	514
<i>Ambika N., Department of Computer Application, SSMRV College, Bangalore, India</i>	
TDSJ-IoT: Trivial Data Transmission to Sustain Energy From Reactive Jamming Attack in IoT	528
<i>Ambika N., Department of Computer Application, SSMRV College, Bangalore, India</i>	
Software Component Technology: Concepts, Design, and Management Method	542
<i>Fadoua Rehioui, University Souldan Moulay Slimane, Morocco</i>	
An Introduction to Clustering Algorithms in Big Data	559
<i>Rajit Nair, Jagran Lakecity University, India</i>	
<i>Amit Bhagat, Maulana Azad National Institute of India, India</i>	
Challenges in Big Data Analysis	577
<i>M. Govindarajan, Annamalai University, India</i>	
Big Data Analytics and IoT in Smart City Applications.....	586
<i>Mamata Rath, Birla School of Management, Birla Global University, India</i>	
Data Streaming Processing Window Joined With Graphics Processing Units (GPUs).....	602
<i>Shen Lu, University of South Florida, USA</i>	
<i>Richard S. Segall, Arkansas State University, USA</i>	

Statistical Techniques for Research.....	624
<i>Jose Carlos Casas-Rosal, Universidad de Córdoba, Spain</i>	
<i>Carmen León-Mantero, Universidad de Córdoba, Spain</i>	
<i>Noelia Jiménez-Fanjul, Universidad de Córdoba, Spain</i>	
<i>Alexander Maz-Machado, Universidad de Córdoba, Spain</i>	

Volume II

Panel Data: A Case Study Analysis	637
<i>Vera Costa, FEUP, University of Porto, Portugal</i>	
<i>Rui Portocarrero Sarmiento, Statsframe, University of Porto, Portugal</i>	
Applications of Decision Support Systems in Aviation.....	658
<i>Tetiana Shmelova, National Aviation University, Ukraine</i>	
<i>Yuliya Sikirda, Flight Academy, National Aviation University, Ukraine</i>	
Classification and Recommendation With Data Streams	675
<i>Bruno Veloso, INESC TEC, Portugal & University Portucalense, Portugal</i>	
<i>João Gama, INESC TEC, Portugal & FEP, University of Porto, Portugal</i>	
<i>Benedita Malheiro, Polytechnic Institute of Porto, Portugal & INESC TEC, Portugal</i>	
N-Tuple Algebra as a Generalized Theory of Relations	685
<i>Boris A. Kulik, Institute for Problems in Mechanical Engineering of RAS, Russia</i>	
<i>Alexander Y. Fridman, Institute for Informatics and Mathematical Modeling of RAS, Russia</i>	
Intelligent Constructing Exact Tolerance Limits for Prediction of Future Outcomes Under Parametric Uncertainty	701
<i>Nicholas Nechval, University of Latvia, Latvia</i>	
The Structure of DNA Taking Into Account the Higher Dimension of Its Components	730
<i>Gennadiy Vladimirovich Zhizhin, Skolkovo, Russia</i>	
Methods and Techniques of Data Mining.....	749
<i>Ana Funes, Universidad Nacional de San Luis, Argentina</i>	
<i>Aristides Dasso, Universidad Nacional de San Luis, Argentina</i>	
Big Data Mining Algorithms.....	768
<i>M. Govindarajan, Annamalai University, India</i>	
Graph Database Management Systems: The Past, the Present, and the Future	778
<i>Kornelije Rabuzin, Faculty of Organization and Informatics, University of Zagreb, Croatia</i>	
<i>Martina Šestak, Faculty of Organization and Informatics, University of Zagreb, Croatia</i>	
New Trends in Databases to NonSQL Databases	791
<i>Antonio Sarasa-Cabezuelo, Facultad de Informática, Universidad Complutense de Madrid, Spain</i>	

EDRC: An Early Data Lending-Based Real-Time Commit Protocol	800
<i>Sarvesh Pandey, MMM University of Technology, India</i>	
<i>Udai Shanker, MMM University of Technology, India</i>	
Application of Data Mining in Smart Grid Technology	815
<i>Lipi Chhaya, Researcher, University of Petroleum and Energy Studies, India</i>	
<i>Paawan Sharma, Pandit Deendayal Petroleum University, India</i>	
<i>Adesh Kumar, University of Petroleum and Energy Studies, India</i>	
<i>Govind Bhagwatikar, Sany Wind Energy India Private Limited, India</i>	
N-Clustering of Text Documents Using Graph Mining Techniques	828
<i>Bapuji Rao, Indira Gandhi Institute of Technology, Sarang, India</i>	
Characterization of Elevated Tumor Markers in Diagnosis of HCC Using Data Mining Methods ...	847
<i>Vyshali J. Gogi, Rashtreeya Vidyalaya College of Engineering, India</i>	
<i>Vijayalakshmi M. N., Rashtreeya Vidyalaya College of Engineering, India</i>	
Designing a Concept-Mining Model for the Extraction of Medical Information in Spanish	856
<i>Olga Acosta, Singularityta SpA, Chile</i>	
<i>César Aguilar, Pontificia Universidad Católica de Chile, Chile</i>	
Overview of Machine Translation Development	874
<i>Irene Rivera-Trigueros, Department of Translation and Interpreting, University of Granada, Spain</i>	
<i>Maria-Dolores Olvera-Lobo, Department of Information and Communication Sciences, University of Granada, Spain</i>	
<i>Juncal Gutiérrez-Artacho, Department of Translation and Interpreting, University of Granada, Spain</i>	
Migrating Software Towards Mobile Technologies.....	887
<i>Liliana Maria Favre, Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina & Comisión de Investigaciones Científicas de la Provincia de Buenos Aires, Argentina</i>	
Interaction Speed as Nonverbal Cues in Text Messaging via Smartphone.....	904
<i>Kiminori Usuki, Tokyo Metropolitan Mizuho Noge High School, Japan</i>	
<i>Shogo Kato, Tokyo Woman's Christian University, Japan</i>	
<i>Yuuki Kato, Sagami Women's University, Japan</i>	
Narrowband Internet of Things.....	913
<i>Sudhir K. Routray, Bule Hora University, Bule Hora, Ethiopia</i>	
Interoperability Provision of IoT Data Protocols on Top of Virtualized Infrastructure.....	924
<i>Vaios Koumaras, INFOLYSiS P.C., Greece</i>	
<i>Marianna Kapari, INFOLYSiS P.C., Greece</i>	
<i>Angeliki Papaioannou, INFOLYSiS P.C., Greece</i>	

<i>George Theodoropoulos, INFOLYSiS P.C., Greece</i>	
<i>Ioannis Stergiou, INFOLYSiS P.C., Greece</i>	
<i>Christos Sakkas, INFOLYSiS P.C., Greece</i>	
<i>Harilaos Koumaras, NCSR “Demokritos”, Greece</i>	
Network Science for Communication Engineering	939
<i>Sudhir K. Routray, Bule Hora University, Bule Hora, Ethiopia</i>	
Application of Biogeography-Based Optimization to Antennas and Wireless Communications	950
<i>Sotirios K. Goudos, Aristotle University of Thessaloniki, Greece</i>	
Bits’ -Carrying Capacities of Switched Local Area Networks	967
<i>Monday Ofori Eyinagho, Afe Babalola University, Nigeria</i>	
<i>Samuel Oluwale Falaki, Afe Babalola University, Nigeria</i>	
Design and Analysis of AWG and FDL-Based Optical Switch in Data Centre Network.....	980
<i>Vaibhav Shukla, Tech Mahindra, Mumbai, India</i>	
<i>Dilip Kumar Choubey, Vellore Institute of Technology, Vellore, India</i>	
Formal Verification of ZigBee-Based Routing Protocol for Smart Grids	1002
<i>Adnan Rashid, National University of Sciences and Technology, Pakistan</i>	
<i>Osman Hasan, National University of Sciences and Technology, Pakistan</i>	
QoS Provisioning for Multicast Routing and Channel Assignment in Wireless Mesh Network.....	1018
<i>Abira Banik, Tripura University, India</i>	
<i>Abhishek Majumder, Tripura University, India</i>	
Evaluating the Effectiveness of Multi-Web Services in Load Balancing Cluster-Based Web Server	1037
<i>Abhijit Bora, Gauhati University, India</i>	
<i>Tulshi Bezboruah, Gauhati University, India</i>	
Challenges and Opportunities of VLC Application in Intelligent Transportation Systems	1051
<i>Aleksandra Kostic-Ljubisavljevic, University of Belgrade, Serbia</i>	
<i>Branka Mikavica, Faculty of Transport and Traffic Engineering, University of Belgrade, Serbia</i>	
Antecedents and Consequences of the Growing Popularity of Digital Consumption	1066
<i>Ritu Narang, University of Lucknow, India</i>	
<i>Sonal Tiwari, University of Lucknow, India</i>	
Television Use and Consumption of Elderly Americans	1085
<i>Robert Andrew Dunn, East Tennessee State University, USA</i>	
<i>Stephen W. Marshall, East Tennessee State University, USA</i>	

Social Media and Social Movements: Strengths, Challenges, and Implications for the Future	1096
<i>Sheldondra J. Brown, Southeast Missouri State University, USA</i>	
<i>Grace M. Babcock, North Carolina State University, USA</i>	
<i>Monica Bixby Radu, Southeast Missouri State University, USA</i>	
Digital Social Networks From a Social Capital Perspective.....	1106
<i>Suparna Dhar, NSHM Knowledge Campus, Kolkata, India</i>	
<i>Indranil Bose, Indian Institute of Management, Kolkata, India</i>	
<i>Mohammed Naved Khan, Aligarh Muslim University, India</i>	
Digital Documents	1118
<i>Anastasios Dimou, Independent Researcher, Athens, Greece</i>	
<i>Apostolos Syropoulos, Greek Molecular Computing Group, Greece</i>	
Digital Media and New Forms of Journalism.....	1130
<i>Lambrini Papadopoulou, Aristotle University of Thessaloniki, Greece</i>	
<i>Theodora A. Maniou, University of Cyprus, Cyprus</i>	
Data Journalism: Definition, Skills, Difficulties, and Perspectives.....	1140
<i>Andreas Veglis, Aristotle University of Thessaloniki, Greece</i>	
<i>Charalampos Bratsas, Aristotle University of Thessaloniki, Greece</i>	
Exploring the Integration of User-Generated Content in Media Organizations Through Participatory Journalism	1152
<i>Theodora A. Saridou, Aristotle University of Thessaloniki, Greece</i>	
<i>Andreas Veglis, Aristotle University of Thessaloniki, Greece</i>	
Adapting a Requirements Engineering Process by Key Factors Estimation.....	1165
<i>Graciela Dora Susana Hadad, Universidad Nacional del Oeste, Argentina & Universidad de Belgrano, Argentina</i>	
<i>Jorge Horacio Doorn, Universidad Nacional de La Matanza, Argentina & Universidad Nacional de Tres de Febrero, Argentina</i>	
<i>Viviana Alejandra Ledesma, Universidad Nacional de La Matanza, Argentina</i>	
Digital Tools Aimed to Represent Urban Survey	1181
<i>Cristina Boido, Politecnico di Torino, Italy</i>	
<i>Pia Davico, Politecnico di Torino, Italy</i>	
<i>Roberta Spallone, Politecnico di Torino, Italy</i>	
Addressing the New Pragmatic Methods in Urban Design Discipline	1196
<i>Hisham Abusaada, Housing and Building National Research Center (HBRC), Egypt</i>	
<i>Abeer Elshater, Ain Shams University, Egypt</i>	
Reengineering Legacy Systems Towards New Technologies.....	1214
<i>Djelloul Bouchiha, Center University of Naama, Algeria & EEDIS Lab. UDL-SBA, Algeria</i>	

A Comprehensive Update and Performance Evaluation of Friction Factor Formulae	1231
<i>Salihu Lukman, University of Hafr Al-Batin, Saudi Arabia</i>	
<i>Isaiah Adesola Oke, Obafemi Awolowo University, Nigeria</i>	
<i>Afolabi M. Asani, Ladoke Akintola University, Nigeria</i>	
The Role of Two-Dimensional Materials in Electromagnetic Interference Shielding.....	1254
<i>Rafael Vargas-Bernal, Instituto Tecnológico Superior de Irapuato, Mexico</i>	
Effect of Nanoparticle and Inclination Angle at Thermal Efficiency in Heatpipes	1271
<i>Sina Razvarz, Department of Automatic Control, Centre for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico</i>	
<i>Raheleh Jafari, School of Design, University of Leeds, Leeds, UK</i>	
<i>Cristóbal Vargas Jarillo, Department of Automatic Control, Centre for Research and Advanced Studies of the National Polytechnic Institute (CINVESTAV-IPN), Mexico City, Mexico</i>	
<i>Alexander Gegov, School of Computing, University of Portsmouth, UK</i>	
Modeling of the Aerodisperse Systems Hydrodynamics in Devices With Directional Motion of the Fluidized Bed	1289
<i>Artem Artyukhov, Sumy State University, Ukraine</i>	
<i>Jan Krmela, Alexander Dubcek University of Trencin, Slovakia</i>	
<i>Nadiia Artyukhova, Sumy State University, Ukraine</i>	
<i>Ruslan Ostroha, Sumy State University, Ukraine</i>	

Volume III

Renewable Resources and Value-Based Complex Forest Management	1309
<i>Yuri P. Pavlov, Institute of Information and Communication Technologies, Bulgarian Academy of Sciences, Bulgaria</i>	
Agriculture 4.0 and Bioeconomy: Strategies of the European Union and Germany to Promote the Agricultural Sector – Opportunities and Strains of Digitization and the Use of Bio-Based Innovations.....	1323
<i>Immo H. Wernicke, German Government (retired), Germany</i>	
Overview of Solid Waste Management of Healthcare and Related Organisations.....	1336
<i>Isaiah Adesola Oke, Obafemi Awolowo University, Nigeria</i>	
<i>Lukman Salihu, University of Hafr Al-Batin, Saudi Arabia</i>	
<i>Idi Dansuleiman Mohammed, Land, Air, and Water Consulting, Nigeria</i>	
<i>Asani M. Afolabi, Ladoke Akintola University, Nigeria</i>	
Managing Water Resources: Industry Initiative.....	1353
<i>Sabyasachi Nayak, Confederation of Indian Industry, India</i>	
Inhibited Antibiotic-Resistant and Electrochemical Treatment of Pharmaceutical Wastewater	1362
<i>Isaiah Adesola Oke, Obafemi Awolowo University, Nigeria</i>	

Fehintola Ezekiel Oluwaseun, Adeyemi Federal University of Education, Ondo, Nigeria
Justinah S. Amoko, Adeyemi Federal University of Education, Ondo, Nigeria
Salihu Lukman, University of Hafr Al-Batin, Saudi Arabia
Adekunbi Enoch Adedayo, Adeyemi Federal University of Education, Ondo, Nigeria

Design and Implementation of a Location-Based Service With Emphasis on a Geographical Database	1384
<i>Wen-Chen Hu, University of North Dakota, USA</i>	
Climate Change: Inclusion of Gender and Cultural Diversity in Climate Change Actions.....	1398
<i>Mgbeodichinma Eucharia Onuoha Oragwa, Technical University of Mining Bergakademie Freiberg, Germany</i>	
Gendering Information and Communication Technologies in Climate Change.....	1408
<i>Sam Wong, University College Roosevelt, The Netherlands</i>	
Science and the Morality of Weapons Research.....	1424
<i>John Forge, University of Sydney, Australia</i>	
Mobilization: Decision Theory	1436
<i>Idongesit Williams, Aalborg University, Denmark</i>	
Moral, Social, and Political Responsibility in the Information Age	1451
<i>Tomas Cahlik, Charles University, Prague, Czech Republic</i>	
The Voice of Social Media, 1997-2018	1461
<i>Bruce Lawrence Cook, Cook Communication, USA</i>	
Breaking Fake News and Verifying Truth	1469
<i>Kazuhiko Shibuya, ROIS, Japan</i>	
Crossfire and Violation of Human Rights in Bangladesh: A Critical Review	1481
<i>Md. Awal Hossain Mollah, University of Rajshahi, Bangladesh</i>	
Politics and Ethics and a National Framework to Combat Corruption in Zimbabwe.....	1497
<i>Tawanda Zinyama, University of Zimbabwe, Zimbabwe</i>	
Good Practices in E-Government Accessibility: Lessons From the European Union.....	1513
<i>Fernando Almeida, Polytechnic Institute of Gaya, Portugal</i> <i>José Augusto Monteiro, Polytechnic Institute of Gaya, Portugal</i>	
National Systems of Innovation Using an Application on EU Data.....	1526
<i>George M. Korres, University of Aegean, Greece</i> <i>Maria P. Michailidis, University of Nicosia, Cyprus</i>	

Comparative Analysis of Applying Behavioral Public Policy to Telecommunication Market by International Organizations.....	1537
<i>Nagayuki Saito, International Professional University of Technology in Tokyo, Japan</i>	
A Good American President	1550
<i>James George, Archway Publishing, USA</i>	
<i>Abdullah Murrar, Indiana University of Pennsylvania, USA</i>	
<i>Pankaj Chaudhary, Indiana University of Pennsylvania, USA</i>	
<i>James Allen Rodger, Indiana University of Pennsylvania, USA</i>	
The Role of DPPs in Promoting Local Government-Citizen Collaboration and Participation: The Case of “Baladiaty”.....	1578
<i>Khaled Tamzini, LaREMFQ Laboratory, IHEC of Sousse, University of Sousse, Tunisia</i>	
<i>Ynes Hafi, ARSELA, Tunisia</i>	
<i>Achref Ben Ouannes, ARSELA, Tunisia</i>	
<i>Roula Borhani, OMEDRH, Tunis, Tunisia</i>	
Local Government, Decentralisation, Devolution, and Service Delivery in Zimbabwe.....	1597
<i>Tawanda Zinyama, University of Zimbabwe, Zimbabwe</i>	
A Risk Management on Demographic Mobility of Evacuees in Disasters.....	1612
<i>Kazuhiko Shibuya, ROIS, Japan</i>	
GIS-Based Quantitative Landslide Risk Assessment Approach for Property and Life at Bartın Hepler.....	1623
<i>Arzu Erener, Kocaeli University, Turkey</i>	
<i>Gülcan Sarp, Süleyman Demirel University, Turkey</i>	
<i>Şebnem Düzgün, Colorado School of Mines, USA</i>	
Technology and the Theory of Apocalypse	1638
<i>Maximiliano Emanuel Korstanje, University of Palermo, Argentina</i>	
Software Literacy as a Vital Digital Literacy in a Software-Saturated World.....	1648
<i>Craig Hight, University of Newcastle, Australia</i>	
<i>Elaine Khoo, The University of Waikato, New Zealand</i>	
ICT Investments on Economic Sectors With International Comparative Advantage and the Diffusion of Prosperity.....	1662
<i>Ioannis Papadopoulos, Metropolitan College, Greece</i>	
<i>Apostolos Syropoulos, Greek Molecular Computing Group, Greece</i>	
Dimensions of the Digital Divide	1672
<i>Marcus Leaning, University of Winchester, UK</i>	
<i>Udo Richard Averweg, eThekweni Municipality, South Africa</i>	

Importance of Digital Literacy and Hindrance Brought About by Digital Divide.....	1683
<i>Mohammad Izzuddin Mohammed Jamil, Universiti Brunei Darussalam, Brunei</i>	
<i>Mohammad Nabil Almunawar, Universiti Brunei Darussalam, Brunei</i>	
Gender Differences in Access to and Use of ICTs in Nigeria.....	1699
<i>Immanuel Ovemeso Umukoro, Lagos Business School, Pan-Atlantic University, Nigeria</i>	
<i>Aanuoluwapo Oluwaseun Omolade-Lawal, University College Hospital, Ibadan, Nigeria</i>	
<i>Samuel Oyelami Babalola, UAC Nigeria Plc, Nigeria</i>	
<i>Kolawole Sunday Akinsumbo, LucrativeTech, Nigeria</i>	
<i>Rashida Mebude Aligwa, Tek Experts Limited, Nigeria</i>	
<i>Balikis Animasaun Abdul-Jeleel, International Institute of Tropical Agriculture (IITA), Nigeria</i>	
How Mobile Technologies Are Leading to Economic Development in Sub-Saharan Africa	1719
<i>Nigel McKelvey, Letterkenny Institute of Technology, Ireland</i>	
<i>Adam Crossan, Letterkenny Institute of Technology, Ireland</i>	
<i>Kevin Curran, Ulster University, UK</i>	
Informational Competencies	1728
<i>José Poças Rascão, Polytechnic Institute of Setúbal, Portugal</i>	
A Primer on Q-Method and the Study of Technology	1746
<i>Stéphanie Gauttier, Grenoble Ecole de Management, France</i>	
Modernizing the Academic Library.....	1757
<i>Jennifer Ashley Wright Joe, University of Toledo, USA</i>	
Prospects and Challenges of Web 3.0 Technologies Application in the Provision of Library Services.....	1767
<i>Promise Ifeoma Ilo, University Library, Pamo University of Medical Sciences, Port Harcourt, Nigeria</i>	
<i>Christopher Nkiko, Elizade University, Nigeria</i>	
<i>Cyprian Ifeanyi Ugwu, University of Nigeria, Nsukka, Nigeria & University of South Africa, South Africa</i>	
<i>Justina Ngozi Ekere, University of Nigeria, Nsukka, Nigeria</i>	
<i>Roland Izuagbe, Covenant University, Nigeria</i>	
<i>Michael O. Fagbohun, Covenant University, Nigeria</i>	
Massive Digital Libraries (MDLs) and the Impact of Mass-Digitized Book Collections.....	1782
<i>Andrew Philip Weiss, California State University, Northridge, USA</i>	

Protocol Development in Clinical Trials for Healthcare Management.....	1797
<i>Swati Changdeo Jagdale, School of Pharmacy, Dr. Vishwanath Karad MIT World Peace University, Pune, India</i>	
<i>Asawaree Anand Hable, MAEER's Maharashtra Institute of Pharmacy, Pune, India</i>	
<i>Anuruddha R. Chabukswar, School of Pharmacy, Dr. Vishwanath Karad MIT World Peace University, Pune, India</i>	
A Regulatory and Safety Perspective on Medical Devices.....	1815
<i>Carla Pires, CBIOS, Universidade Lusófona, Portugal</i>	
<i>Dinah Duarte, CBIOS, Universidade Lusófona, Portugal</i>	
Medical Social Networks, Epidemiology and Health Systems.....	1827
<i>Patrícia C. T. Gonçalves, INESC TEC, University of Porto, Portugal</i>	
<i>Ana S. Moura, LAQV-REQUIMTE, University of Porto, Portugal</i>	
<i>M. Natália D. S. Cordeiro, LAQV-REQUIMTE, University of Porto, Portugal</i>	
<i>Pedro Campos, INESC TEC, University of Porto, Portugal</i>	
Ambiguities in the Privacy Policies of Common Health and Fitness Apps	1839
<i>Devjani Sen, Algonquin College, Canada</i>	
<i>Rukhsana Ahmed, University at Albany, SUNY, USA</i>	
Generosity in Healthcare Policy Under the Obama Administration: Reflecting Various Dimensions Focused on the ACA.....	1850
<i>Khadijeh Roya Rouzbehani, University of Victoria, Canada</i>	
Islamic Medical Ethics in Brunei Darussalam Hospitals	1860
<i>Syazana Fauzi, Universiti Brunei Darussalam, Brunei</i>	
Distribution of Selected Health Technology in Regions of Slovakia	1872
<i>Beata Gavurova, Technical University of Košice, Slovakia</i>	
<i>Matus Kubak, Technical University of Kosice, Slovakia</i>	
Expanding Scope of Information Technology in Clinical Care.....	1888
<i>Gumpeny R. Sridhar, Endocrine and Diabetes Centre, Visakhapatnam, India</i>	
Artificial Neural Networks in Medicine: Recent Advances.....	1901
<i>Steven Walczak, University of South Florida, USA</i>	
Internet of Things and Data Science in Healthcare	1919
<i>George Tzanis, Aristotle University of Thessaloniki, Greece</i>	
<i>Ourania-Ioanna Fotopoulou, Aristotle University of Thessaloniki, Greece</i>	
Internet of Things in Healthcare as an Innovative Form of Personalized Medicine.....	1933
<i>Ljubica Dikovic, College of Applied Sciences Uzice, Serbia</i>	

Highly Aged and After Cloud	1944

Preface

As our world continues its inexorable progression, advancements in all areas of science particularly in the field of information science and technology are rapidly revolutionizing the way the human population interacts, conducts business, governs, and maintains health and well-being. A driving force across all fields and industries continues to be technological innovations which constantly disrupt contemporary theories, methods, and practices, and persistently replaces them with more effective and efficient applications. This has been true more than ever during the recent global crises impacting all facets of life and business.

Understanding information science and technology (IS&T) and its most recent advancements is paramount to improving knowledge and expanding the way human minds think, subsist, and evolve, providing mankind with so many new methods of information and knowledge management. Obviously, the rapid rate of innovations and expansion in the utilization and management of information science and technologies requires a profound understanding of every aspect of knowledge related to the latest research and discoveries within this very important field of study.

To examine the evolution of this publication from its first inaugural release to the present can provide a good understanding of research progressions and the overall value of this latest edition. The first edition of the *Encyclopedia of Information Science and Technology (First Edition)* was released in early 2005 and was comprised of five volumes of invaluable knowledge on breakthroughs, discoveries, and authoritative research results in technological advancements. It positioned itself as the first of its kind in reference publications and supplied researchers with a definitive one-stop reference source. Following the success of the first edition, the *Encyclopedia of Information Science and Technology (Second Edition)* was released in late 2008. It included eight volumes of updated research on crucial topics previously covered in the first edition, as well as an examination of new developments, technologies, and areas of research, allowing the second edition to surpass the first in terms of timeliness, comprehensiveness, and critical acclaim.

Seven years later, the field of information science and technology had progressed so rapidly that ten volumes of completely new content uncovering the most current research findings related to technological, organizational, and managerial issues, challenges, trends, and applications was needed. All-encompassing and lauded as an essential reference for any academic library, the *Encyclopedia of Information Science and Technology (Third Edition)* bridged existing gaps in available references by covering paradigms that were shaping the ever-changing research, theory, and discovery of IS&T.

In 2018, technology had become so ubiquitous and relied upon so heavily by society, that a new edition of the *Encyclopedia of Information Science and Technology (Fourth Edition)* was not only warranted, but demanded by researchers looking to remain up-to-date in a field that had grown by leaps

and bounds in only three short years. Comprised once again of ten volumes and sharing expert research from contributions obtained worldwide, this well-established reference source investigated the most forward-thinking and diverse findings on the impact of information science and new technologies in modern settings that cross all sectors of society, including education, healthcare, government, engineering, business, and physical sciences.

As technology continued to advance and disrupt society at a rapid pace, it was observed that once again, an updated edition in this expansive field was needed. However, this time, the advancements made to businesses and organizations were so extensive, and the content that was acquired from prominent researchers across various areas was so great, it was decided that the encyclopedia would need to be split into two different encyclopedias. A smaller and more precise three-volume *Encyclopedia of Information Science and Technology (Fifth Edition)* that centers on the newest technological innovations and their applications in fields such as medicine, library science, security, and government and another larger five-volume encyclopedia, the *Encyclopedia of Organizational Knowledge, Administration, and Technologies*, that is focused primarily on business and organizational aspects, with both of these encyclopedias offering a greater overall level of accessibility and focus to the readership.

The three-volume *Encyclopedia of Information Science and Technology (Fifth Edition)* is composed of 136 expert peer-reviewed chapters that provide a balanced representation of concepts and issues from researchers around the world. For this edition and all that preceded it, these specially invited researchers were asked to submit proposals describing the topic and scope of their chapters. Each submitted chapter was forwarded to at least three expert external reviewers on a double-blind peer review basis. Only submissions with strong and favorable reviews were chosen as chapters for this edition. In some cases, submissions were sent back for several revisions prior to final acceptance. The goal was to assemble the best minds in the information science and technology field from all over the world to contribute chapters to this encyclopedia and to apply the highest level of quality in selecting chapters for inclusion.

This edition of the *Encyclopedia of Information Science and Technology* only contains previously unpublished research on the most emerging insights in the area of information science and technology, exploring in depth the new methods and processes for understanding modern technological tools and their applications as well as emerging theories and ethical controversies. Academicians, professionals, researchers, librarians, policy makers, and students are all targeted beneficiaries of this extensive encyclopedia, especially those working in the fields of computer science, engineering, library science, medicine, medical technologies, environmental science, ethics, data science, security and forensics, media and communications, government, crisis management, and the social sciences, to name a few. With its vast coverage of conceptual, methodological, and technical aspects of IS&T, including but not limited to such cutting-edge topics as gene editing, the Internet of Things, social media, fake news, natural language processing, digital consumption, Big Data, smart cities, cyberbullying, autonomous vehicles, deep learning, algorithms, cyberterrorism, machine learning, and information privacy, the chapters within this publication are sure to provide readers the tools necessary for further research and discovery in their respective industries and/or fields.

The *Encyclopedia of Information Science and Technology, Fifth Edition* is organized into sixteen sections that provide comprehensive coverage of important topics. These sections are: 1) Artificial Intelligence; 2) Computational Science; 3) Cyber Crime, Cyber Bullying, and Digital Terrorism; 4) Cyber Security and Data Protection; 5) Data Management, Analysis, and Statistics; 6) Data Mining and Databases; 7) Digital and Wireless Communications; 8) Digital Media; 9) Engineering Science and Technologies; 10) Environmental Science and Technologies; 11) Ethics and Social Responsibility; 12)

Government, Policy, and Crisis Management; 13) Human Aspects of Technology; 14) Library Science and Research Methods; 15) Medical Ethics and Law; and 16) Medical Technologies.

Each of the focused sections include diverse chapters centered around a common theme, with each of the chapters then arranged by relevance to the theme and to each other. Two different tables of contents support the reader with navigating the contents by volume and alphabetically. Also, technical, and managerial terms and their definitions are offered in addition to thorough reference sections.

Below are just a few highlighted chapter contributions within each of the sections:

SECTION 1: ARTIFICIAL INTELLIGENCE

This section opens this extensive reference source by highlighting some of the latest advancements taking place in artificial intelligence and its applications across a variety of industries. The opening chapter of this section is titled, “**Autonomous Vehicles,**” authored by Prof. Yair Wiseman of Bar-Ilan University, Israel, which discusses improvements made to modern vehicles that allows them to be converted to entirely automatic systems. Another chapter in this section, “**Human-Agent-Robot Teamwork (HART) over FiWi Based Tactile Internet Infrastructures,**” authored by Mr. Chowdhury Mahfuzulhoq and Dr. Martin Maier, of the Institut National de la Recherche Scientifique, Canada, discusses related work and open challenges for latency-sensitive HART task. The next chapter, “**Embedded Control System Design for Inverted Pendulum Type Mobile Robots Based on High-Level Petri Nets,**” authored by Prof. Gen’ichi Yasuda of Nagasaki Institute of Applied Science, Japan, examines a unified method for designing nonlinear motion control software of traveling control by non-holonomic two-wheeled inverted pendulum mobile robots, where self-balancing control is designed with a backstepping approach is presented. Another chapter within this section, “**Text Based Image Retrieval Using Deep Learning,**” authored by Mr. Udit Singhania and Prof. B Tripathy from Vellore Institute of Technology, India, discusses recurrent neural nets, deep restricted Boltzmann machines, and general adversarial nets and how they revolutionize the field of information retrieval. Concluding this section is the chapter, “**Acoustic Presence Detection in a Smart Home Environment,**” authored by Profs. Andrej Zgank and Damjan Vlaj of the University of Maribor, Slovenia. This chapter presents information on acoustic presence detection that can be used to optimize the smart home human-computer interface with personalization and customization functionalities.

SECTION 2: COMPUTATIONAL SCIENCE

This section includes chapters that investigate recent developments within mathematical models and their ability to solve scientific problems. This section begins with the chapter, “**Sense and Boundaries of Computer Simulations,**” authored by Dr. Apostolos Syropoulos from the Greek Molecular Computing Group, Greece, which examines why computer simulation boundaries happen, how they can be solved, and whether the “ultimate” goal of simulating the whole universe is feasible. In a following chapter, “**A General-Purpose Uniform Random Number Package,**” authored by Dr. E. Jack Chen of the BASF Corporation, United States, examines generating sequences of pseudorandom numbers as a fundamental part of computer simulation systems. In another chapter, “**Tuning Drone Data Delivery and Analysis on the Public Cloud,**” authored by Prof. Jose Lo Huang from Simon Bolivar University,

Venezuela, a set of self-developed software written in Python, C, and Bash is used to improve the speed of data transmission and analysis of drone generated videos, taken in eight different cities in America, to the public cloud of Amazon Web Services. A following chapter, **“Modeling of Uncertain Nonlinear System with Z-numbers,”** authored by Prof. Raheleh Jafari, from the University of Leeds, United Kingdom, Dr. Sina Razvarz of CINVESTAV-IPN (National Polytechnic Institute), Mexico, Prof. Alexander Gegov from University of Portsmouth, United Kingdom, and Prof. Satyam Paul of Orebro University, Sweden, examines how fuzzy equations with Z-number coefficients are used in order to model the fuzzy nonlinear systems. In the next and final chapter in this section, **“Use of Grey Numbers for Evaluating a System’s Performance under Fuzzy Conditions,”** authored by Prof. Michael Voskoglou of the Graduate Technological Educational Institute (T.E.I.), Greece, a method using Grey Numbers as tools is developed for assessing a system’s mean performance, which is useful when utilizing qualitative grades and not numerical scores for this purpose.

SECTION 3: CYBER CRIME, CYBER BULLYING, AND DIGITAL TERRORISM

This section presents a collection of chapters that define cyberbullying and cyber terrorism, exploring the consequences of these online attacks and crimes, and suggests potential remedies in combating this phenomenon. The first chapter opening this section, **“Cyber Profiling in Criminal Investigation,”** authored by Prof. Szde Yu of Wichita State University, United States, introduces what cyber profiling is and how it can help with criminal investigation. A following chapter, **“Cyberbullying,”** authored by Prof. Michelle Wright of Pennsylvania State University, United States, examines and defines cyberbullying among children and adolescents by utilizing multidisciplinary qualitative, quantitative, and mixed-design research methodologies. Another chapter within this section, **“How Theoretical Frameworks Inform the Understanding of the Relationship Between Gender and Cyberbullying,”** authored by Profs. Monica Radu and Alexandria Rook of Southeast Missouri State University, United States, uses an interdisciplinary approach to examine gender differences in cyberbullying and the implications this has for future research and policy development. Concluding this section is the final chapter, **“The Human Rights Based Approach to Combat Cyberbullying Against Women and Girls,”** authored by Prof. Yuen Luk of Nanyang Technological University, Singapore, which explores the adoption of a human rights based approach to fighting against cyberbullying and encouraging the rights to privacy and freedom of expression online for women.

SECTION 4: CYBER SECURITY AND DATA PROTECTION

This section discusses the dangers of cyber-attacks by offering methods and frameworks that can be used to improve cyber security and ensure the protection of data and information online. Opening this section is the chapter, **“Hexa-Dimension Metric, Ethical Matrix, and Cybersecurity,”** authored by Prof. Wanbil Lee of The Computer Ethics Society and Wanbil & Associates, Hong Kong, which develops an ethics-based framework as a remedy to mitigate hacking in cyberspace and illustrates the tools of the Ethical Matrix and Hexa-dimension Metric using the Octopus Saga. The next chapter, **“A Utility Theory of Privacy and Information Sharing,”** authored by Prof. Julia Puaschunder of The New School, United States, covers the problem of individuals’ decisions to share information about themselves on

social media and how big data administrators reap the benefits from putting data together over time. A following chapter, **“The 2018 Facebook Data Controversy and Technological Alienation”**, authored by Profs. Ananda Mitra and Yasmine Khosrowshahi of Wake Forest University, United States, uses the issues surrounding the controversy as a point of departure to explore two related issues – first the way in which the “technologically alienated” individual makes technological decisions without being mindful of the consequences of the technological choices and secondly the way in which the alienation can be utilized to obtain detailed information from the structured and unstructured data that makes up the gigantic corpus of Big Data. Another chapter is, **“Forensic Acquisition Methods for Cloud Computing Environments,”** authored by Prof. Diane Barrett of Bloomsburg University of Pennsylvania, United States. This chapter explores current forensic acquisition processes, how current processes need to be modified for cloud investigations, and what new acquisition methods can help garner evidence from a cloud computing-based environment. The final chapter in this section, **“TDSJ-IoT - Trivial Data Transmission to Sustain Energy from Reactive Jamming Attack in IoT,”** authored by Prof. Ambika Nagaraj of the SSMRV Degree College, India, proposes a method to minimize jamming attacks in the Internet of Things by increasing the reliability of communication, increasing overall effectiveness, and minimizing the energy needed to combat attacks.

SECTION 5: DATA MANAGEMENT, ANALYSIS, AND STATISTICS

This section provides many chapters on the modern utilization of statistical models in assessing the utility and usefulness of data and identifying new approaches and software that can best be used for data management. The first chapter in this section, **“Software Component Technology,”** authored by Prof. Fadoua Rehioui of the University Soultan Moulay Slimane, Morocco, discusses the development of information systems, by their data, and the resultant knowledge by proposing a component identification approach and the management component for data management. In a following chapter, **“Data Streaming Processing Window Join with Graphics Processing Units (GPUs),”** authored by Prof. Shen Lu of the University of South Florida, United States and Prof. Richard Segall from Arkansas State University, United States, covers research that discusses the continuous case of big data often called “Data Streaming” and utilizes the algorithmic side of data stream processing. The next chapter, **“Statistical Techniques for Research,”** authored by Profs. Jose Casas-Rosal, Carmen León-Mantero, Noelia Jiménez-Fanjul, and Alexander Maz-Machado of the University of Córdoba, Spain, creates a classification of the main statistical techniques used in different research fields, adds a brief definition of them and specifies their utility, the data hypothesis needed for their use, and software required. Another chapter within this section, **“Classification and Recommendation with Data Streams,”** authored by Prof. Bruno Veloso of University Portucalense, Portugal, Prof. João Gama of INESC TEC - FEP, Portugal, and Prof. Benedita Malheiro from the Polytechnic Institute of Porto, Portugal, addresses data stream knowledge processing, covers classification, recommendation and evaluation, describes existing algorithms/techniques, and identifies open challenges. The concluding chapter in this section, **“The Structure of DNA Taking into Account the Higher Dimension of Its Components,”** authored by Prof. Gennadiy Zhizhin of Skolkovo, Russian Federation, shows representations and images of the higher dimensionality of the constituent DNA molecules (D - ribose and phosphoric acid ion) described mathematically.

SECTION 6: DATA MINING AND DATABASES

This section features chapters that investigate data mining, including the tasks and techniques associated, as well as exploring more advanced methodologies in managing database systems more effectively and efficiently. Opening this section is the chapter, **“Methods and Techniques of Data Mining,”** authored by Profs. Ana Funes and Aristides Dasso of the Universidad Nacional de San Luis, Argentina. This chapter compares data mining with other disciplines while also providing an overview and classification of data mining tasks and methods complete with issues associated to the discipline and future research directions. The next chapter in this section, **“Graph Database Management Systems – the Past, the Present and the Future,”** authored by Profs. Kornelije Rabuzin and Martina Šestak of the University of Zagreb, Faculty of Organization and Informatics, Croatia, gives a timeline overview of developed graph data storage solutions in order to gain insight into past, present, and future trends of GDBMSs. The next chapter, **“New Trends in Databases to NonSQL Databases,”** authored by Prof. Antonio Sarasa-Cabezuelo of Universidad Complutense de Madrid, Spain, introduces the NonSQL databases currently being used as an alternative to solving the needs raised in the context of big data without the limitations of relational databases. Another chapter in this section, **“Application of Data Mining in Smart Grid Technology,”** authored by Profs. Lipi Chhaya, and Adesh Kumar of UPES, India, Prof. Paawan Sharma of PDP, India, and Prof. Govind Bhagwatikar from Sany Wind Energy India Private Limited, India, explains how data mining techniques can be an effective solution for operation and management in smart grids. Finishing out the section is the chapter, **“Designing a Concept Mining Model for the Extraction of Medical Information in Spanish,”** authored by Prof. Olga Acosta, Singularityta SpA, Chile and Prof. César Aguilar, Pontificia Universidad Católica de Chile, Chile, which sketches the development of a method for mining concepts applied on medical corpora in Spanish, particularly the extraction of specialized terms and the identification of lexical-semantic relationships, in concrete hyponymy/hypernymy and meronymy.

SECTION 7: DIGITAL AND WIRELESS COMMUNICATIONS

This section features chapters that define the many modes of digital and wireless communications and presents a variety of methods, approaches, and solutions for optimizing its usage. Starting this section is the chapter, **“Overview of Machine Translation Development,”** authored by Profs. Irene Rivera-Trigueros, María-Dolores Olvera-Lobo, and Gutiérrez-Artacho from the University of Granada, Spain. This chapter provides an overview of Machine Translation (MT) development since its early beginnings in the late 1950s until present day and reviews the evolution of MT techniques starting from traditional approaches. A following chapter is, **“Interaction Speed as Nonverbal Cues in Text Messaging Via Smartphone,”** authored by Mr. Kiminori Usuki of Tokyo Metropolitan Mizuho Noge High School, Japan, Dr. Shogo Kato from Tokyo Woman’s Christian University, Japan, and Dr. Yuuki Kato, Sagami Women’s University, Japan. This chapter focuses on the speed of interaction in text messaging via smart phone applications, specifically those with read receipt functions, and future directions in examining the strategic use of speed of interaction and read receipts. The next chapter, **“Narrowband Internet of Things,”** authored by Dr. Sudhir Routray of AASTU, Addis Ababa, Ethiopia, explores the main features of narrowband IoT (NB-IoT), the greener and more efficient version of IoT, and its potential and applications across different domains. The next chapter in this section, **“Application of Biogeography-based**

Optimization to Antennas and Wireless Communications,” authored by Prof. Sotirios Goudos of the Aristotle University of Thessaloniki, Greece, describes the biogeography-based optimization algorithm and presents its application to antenna and wireless communications design problems. The section ends with the chapter, **“Challenges and Opportunities of VLC Application in Intelligent Transportation Systems,”** authored by Profs. Aleksandra Kostic-Ljubisavljevic and Branka Mikavica of the University of Belgrade Serbia, which presents an analysis of the possibilities of VLC application in ITS scenarios and defines the main characteristics of VLC in ITS in terms of architecture, modulation, and standardization.

SECTION 8: DIGITAL MEDIA

This section features a collection of chapters that explores the effects of digital media as it becomes more engrained in today’s world and continues advancing rapidly along with its significant impact on individuals, society, and all facets of life on this earth. The first chapter in this section is, **“Antecedents and Consequences of Growing Popularity of Digital Consumption,”** authored by Dr. Ritu Narang and Miss Sonal Tiwari of the University of Lucknow, India. It proposes a conceptual model to extend knowledge about the antecedents and consequences of internet television consumption and its implications for individuals as well as society. The following chapter, **“Television Use and Consumption of Elderly Americans,”** authored by Profs. Robert Dunn and Stephen Marshall of East Tennessee State University, United States, presents research that offers a state of the art review on the elderly and their consumption of television, including new advancements in the media, potential motivations, and resulting effects. The next chapter, **“Social Media and Social Movements,”** authored by Ms. Sheldondra Brown and Dr. Monica Radu of Southeast Missouri State University, United States and Ms. Grace Babcock of North Carolina State University, United States, introduces the concepts of social media and social movements and also reviews recent literature examining how social media plays an active role in creating and encouraging those social movements. The following chapter, **“Digital Social Networks from a Social Capital Perspective,”** authored by Profs. Suparna Dhar and Mohammed Naved Khan of Aligarh Muslim University, India and Prof. Indranil Bose of the Indian Institute of Management, Kolkata, India, explores the unique opportunities offered by digitization of social networking, the novel capabilities of information dissemination and foraging on DSN sites, and the widespread adoption that necessitates theoretical interpretation of antecedents and consequences of DSN adoption. Concluding the section is the chapter, **“Exploring the Integration of User-Generated Content in Media Organizations Through Participatory Journalism,”** authored by Mrs. Theodora Saridou and Prof. Andreas Veglis of Aristotle University of Thessaloniki, Greece, which offers an in-depth description of the concept of participatory journalism, which holds an important and constantly evolving part in the digital media production.

SECTION 9: ENGINEERING SCIENCE AND TECHNOLOGIES

This section includes emerging research on technological tools and scientific methods that are expanding the field of engineering science. Opening this section is the chapter, **“Adapting a Requirements Engineering Process by Key Factors Estimation,”** authored by Dr. Graciela Hadad of both Universidad Nacional del Oeste and Universidad de Belgrano, Argentina, Prof. Jorge Doorn from Universidad Nacional del Oeste, Argentina, and Prof. Viviana Ledesma from Universidad Nacional de La Matanza, Argentina,

which proposes a process for constructing and dynamically adapting a requirements process, focusing on the evolving factors. The following chapter, **“Digital Tools Aimed to Represent Urban Survey,”** authored by Profs. Cristina Boido, Pia Davico, and Roberta Spallone of Politecnico di Torino, Italy, compares the knowledge and informative capabilities of different new technologies for urban modeling, through an overview of international researches, case studies, and personally conducted experiences. The next chapter in this section, **“Reengineering Legacy Systems Towards New Technologies,”** authored by Prof. Djelloul Bouchiha from Centre Universitaire De Naama SALHI Ahmed, Algeria, presents all the concepts, techniques and analyses in relation to the problem of re-engineering existing (legacy) systems toward new technologies. A following chapter, **“The Role of Two-Dimensional Materials in Electromagnetic Interference Shielding,”** authored by Dr. Rafael Vargas-Bernal from the Instituto Tecnológico Superior de Irapuato, Mexico, describes the impact that two-dimensional materials (or 2D materials) are having on the development of materials used for electromagnetic interference shielding, particularly the impulse of materials such as graphene, MXenes, transition metal dichalcogenides (TMDs), and phosphorene. The final chapter of the section, **“Modeling of the Aerodisperse Systems Hydrodynamics in Devices with Directional Motion of the Fluidized Bed,”** authored by Profs. Artem Artyukhov, Nadiia Artyukhova, and Ruslan Ostroha from Sumy State University, Ukraine and Prof. Jan Krmela from Alexander Dubcek University of Trencin, Slovakia, examines the usage of modern program packages for simulation of the aerodisperse systems hydrodynamics of equipment with directional motion of the fluidized bed for the chemical industry.

SECTION 10: ENVIRONMENTAL SCIENCE AND TECHNOLOGIES

This section highlights the newest innovations, strategies, and tools that are being used to mitigate pollution and examine the impacts of climate change in order to build a more sustainable global environment. The first chapter in this section, **“Renewable Resources and Value Based Complex Forest Management,”** authored by Dr. Yuri Pavlov from the Bulgarian Academy of Sciences, Bulgaria, investigates the question of multifactor value driven management of renewable resources of complex forest systems. A following chapter, **“Overview of Solid Waste Management of Healthcare and Related Organization,”** authored by Prof. Isaiah Oke from Obafemi Awolowo University, Nigeria, Prof. Lukman Salihu of University of Hafr Al-Batin, Saudi Arabia, Mr. Idi Mohammed from Land, Air and Water Consulting, Nigeria, and Prof. Asani Afolabi from Ladoke Akintola University, Nigeria, provides information on the quantities and properties of healthcare wastes in various types of facilities located in developing countries, as well as in some industrialized countries. The next chapter, **“Managing Water Resources by Industry Initiative,”** written by Dr. Sabyasachi Nayak of the Confederation of Indian Industry, India, seeks to capture the grassroots interventions undertaken by industry in improving the management of water resources. Another chapter in this section, **“Design and Implementation of a Location-Based Service with Emphasis on a Geographical Database,”** authored by Prof. Wen-Chen Hu of the University of North Dakota, United States, tries to mitigate the high difficulty of location-based service construction by showing the construction step by step with a focus on connecting a mobile device to a server-side geographical database. The final chapter in this section, **“Gendering Information and Communication Technologies in Climate Change,”** authored by Prof. Sam Wong of the University College Roosevelt, Netherlands, explains why, and how, women are more constrained than men from using ICTs in tackling climate change.

SECTION 11: ETHICS AND SOCIAL RESPONSIBILITY

This section provides thoughtful discussions on the ethical applications of technologies within society and the moral consequences and challenges they can present. The first chapter in this section is, **“Science and the Morality of Weapons Research,”** authored by Prof. John Forge of the University of Sydney, Australia. In this chapter the author attempts to answer the question: Is it ever morally justified to design the means to kill, harm and destroy, and if so, under precisely what circumstances? In a following chapter, **“Moral, Social and Political Responsibility in the Information Age,”** authored by Prof. Tomas Cahlik of Charles University Prague, Czech Republic, effects of ICTs on the responsibilities of living a good life and being a good person and having efficient and just social structures are discussed. Another chapter in this section, **“The Voice of Social Media, 1997-2018,”** authored by Dr. Bruce Cook of Cook Communications, United States, highlights a discussion on the consideration of social media censorship and questions of freedom of expression. In the next chapter, **“Breaking Fake News and Verifying Truth,”** authored by Dr. Kazuhiko Shibuya of ROIS, Japan, online fact-checking studies on fake news are reviewed. The concluding chapter in this section, **“Politics and Ethics and a National Framework to Combat Corruption in Zimbabwe,”** authored by Prof. Tawanda Zinyama from the University of Zimbabwe, Zimbabwe, seeks to interrogate issues of politics and ethics because they have a bearing on the realization or lack thereof of the Zimbabwean Vision 2030.

SECTION 12: GOVERNMENT, POLICY, AND CRISIS MANAGEMENT

This section examines government policies and practices and explores future opportunities and lessons learned from recent disasters around the world for the development of better crisis response management. Opening this section is the chapter, **“Good Practices in e-Government Accessibility,”** authored by Profs. Fernando Almeida and José Monteiro from the Polytechnic Institute of Gaya, Portugal, which looks to the accessibility of good practices that should be adopted in the development of e-Government platforms. The next chapter in this section, **“National Systems of Innovation Using an Application on EU Data,”** authored by Prof. George Korres from the University of Aegean, Gabon and Prof. Maria Michailidis from the University of Nicosia, Cyprus, reviews the theory and the current literature of the national systems of innovation and attempts to apply some statistical measurement and indices in order to estimate the effects and the implications on EU innovation systems member states. The following chapter, **“Comparative Analysis of Applying Behavioral Public Policy to Telecommunication Market by International Organizations,”** authored by Dr. Nagayuki Saito from the International Professional University of Technology in Tokyo, Japan, reviews the status of behavioral public policy being introduced in each international organization and compares and verifies the stages of behavioral public policy in terms of consumer protection policy in each international organization in the telecommunications market. The next chapter, **“A Good American President,”** authored by Mr. James George, Archway Publishing, United States and Mr. Abdullah Murrar, Dr. Pankaj Chaudhary, and Dr. James Rodger from the Indiana University of Pennsylvania, United States, describes political engineering at an atomic level; that is, addressing what makes a competent elected official and using the office of president of the United States as an example. The concluding chapter of this section, **“A Risk Management on Demographic Mobility of Evacuees in Disaster,”** authored by Dr. Kazuhiko Shibuya of ROIS, Japan, describes both

risks and crises on disaster and specifically reviews issues and discusses future design for the lessons from the Fukushima nuclear power plant accident.

SECTION 13: HUMAN ASPECTS OF TECHNOLOGY

This section discusses societal utilization of technology and the impact it has on social and economic development across the globe. Opening this section is the chapter, **“The Technology and the Theory of Apocalypse,”** authored by Prof. Maximiliano Korstanje of the University of Palermo, Argentina. It ignites an interesting discussion around the idea of apocalypse connection to the role of technology in slicing humanity from nature. The next chapter in this section, **“Software Literacy as a Vital Digital Literacy in a Software-Saturated World,”** authored by Prof. Craig Hight from the University of Newcastle, Australia and Prof. Elaine Khoo of The University of Waikato, New Zealand, proposes the notion of ‘software literacy’ to highlight a neglected aspect of digital literacies and a key means of conceptualizing the skills and understandings needed for people to be critical and creative users of software in today’s software saturated culture. The following chapter, **“ICT Investments on Economic Sectors with International Comparative Advantage and the Diffusion of Prosperity,”** authored by Dr. Apostolos Syropoulos of the Greek Molecular Computing Group, Greece, shows how Information Communication and Technologies (ICTs) can be used to boost the economy of a country that emerges from a deep crises. In the next chapter, **“Dimensions of the Digital Divide,”** authored by Prof. Marcus Leaning from the University of Winchester, United Kingdom and Mr. Udo Averweg of eThekweni Municipality, South Africa, the authors claim that the idea of the digital divide can be understood to operate in a range of different ‘dimensions’ and argue that the problem is a multi-faceted one which requires a multi-level approach to address. The concluding chapter in this section, **“How Mobile Technologies are Leading to Economic Development in Sub-Saharan Africa,”** authored by Prof. Nigel McKelvey and Mr. Adam Crossan from the Letterkenny Institute of Technology, Ireland and Prof. Kevin Curran from Ulster University, United Kingdom, investigates the use of mobile technology to help residents of sub-Saharan Africa in the sectors of health care and education.

SECTION 14: LIBRARY SCIENCE AND RESEARCH METHODS

This section presents the latest research findings in methodologies and techniques in managing informational competencies and Q-method, as well as the impact that technology has had on libraries worldwide. The first chapter in this section, **“Informational Competencies,”** authored by Prof. José Rascão from the Polytechnic Institute of Setúbal, Portugal, studies the informational competences and processes of its construction, transmission, and use, based on the aggregation of existing literature. The following chapter, **“A primer on Q-method and the Study of Technology,”** authored by Dr. Stéphanie Gauttier of Grenoble Ecole de Management, France, provides an in-depth description of Q-method and demonstrates how its use could be beneficial to studies of technology and could reinforce the transparency and validity of other qualitative methods. The next chapter in this section, **“Modernizing the Academic Library,”** authored by Prof. Jennifer Joe of University of Toledo, United States, examines libraries and their response to change and thinking outside of the box when it comes to their employees, their resources, and their mission statements in order to meet the challenges that the digital age presents. The

following chapter in this section, **“Prospects and Challenges of Web 3.0 Technologies Application in the Provision of Library Services,”** authored by Prof. Promise Ilo, Mr. Roland Izuagbe, and Mr. Michael Fagbohun, from Covenant University, Nigeria, Prof. Christopher Nkiko of Elizade University, Nigeria, and Profs. Cyprian Ugwu and Ngozi Ekere from the University of Nigeria Nsukka, Nigeria, provides an in-depth description of Q-method and demonstrates how its use could be beneficial to studies of technology and could reinforce the transparency and validity of other qualitative methods. The final chapter in this section, **“Massive Digital Libraries (MDLs) and the Impact of Mass-Digitized Book Collections,”** authored by Mr. Andrew Weiss of California State University, Northridge, United States, describes the characteristics of Massive Digital Libraries (MDLs) and outlines their impact upon current information science issues, especially digital collection metadata, copyright and fair use, the diversity of source collections, and user privacy.

SECTION 15: MEDICAL ETHICS AND LAW

This section contains forward-thinking research on new medical policies and laws as well as ethical issues that have recently been presented in the regulation of medical devices, technologies, and patient information. The opening chapter of this section is, **“Protocol Development in Clinical Trials for Healthcare Management,”** authored by Dr. Swati Jagdale and Dr. Anuruddha R. Chabukswar from the Dr. Vishwanath Karad MIT World Peace University, India and Miss Asawaree Anand Hable of MAEER’s Maharashtra Institute of Pharmacy, India, which discusses the development of protocols for clinical trials to serve as a roadmap for healthcare professionals involved in investigation work. The following chapter, **“Ambiguities in the Privacy Policies of Common Health and Fitness Apps,”** authored by Prof. Devjani Sen from Algonquin College, Canada and Prof. Rukhsana Ahmed from the University of Albany, SUNY, United States, provides a set of recommendations when designing privacy policies for the sharing of personal information collected from health and fitness apps. The next chapter, **“Generosity in Healthcare Policy under the Obama Administration,”** authored by Prof. Khadijeh Rouzbehani from the University of Victoria, Canada, examines the Affordable Care Act as an improved alternative to the previous policy regime on healthcare in the United States. The following chapter, **“Islamic Medical Ethics in Brunei Darussalam Hospitals,”** authored by Prof. Syazana Fauzi of Universiti Brunei Darussalam, Brunei, seeks to analyze whether Brunei Darussalam’s health professionals handle medical ethical cases in a manner that is congruent to the State Mufti’s fatāwā. The final chapter in this section, **“Distribution of Selected Health Technology in Regions of Slovakia,”** authored by Profs. Beata Gavurova and Matus Kubak from the Technical University of Košice, Slovakia, deals with the issue of regional disparities in the use of selected medical technology.

SECTION 16: MEDICAL TECHNOLOGIES

This section contains the most recent research on the latest technologies utilized and applied in healthcare for the more efficient and effective diagnosis and treatment of diseases and illnesses. The first chapter in this section, **“Expanding Scope of Information Technology in Clinical Care,”** authored by Dr. Gumpeny Sridhar of the Endocrine and Diabetes Centre, India, describes the genesis and evolution of an electronic medical record (EMR) system at the Endocrine and Diabetes Centre and proposes ways

in which the existing system can be further developed with additional features. A following chapter, **“Artificial Neural Networks in Medicine - Recent Advances,”** authored by Prof. Steven Walczak from the University of South Florida, United States, examines recent trends and advances in Artificial Neural Networks (ANN) and provides references to a large portion of recent research, as well as looking at the future direction of research for ANN in medicine. The next chapter, **“Internet of Things and Data Science in Health Care,”** authored by Dr. George Tzanis and Mrs. Ourania-Ioanna Fotopoulou of Aristotle University of Thessaloniki, Greece, introduces the Cloud-IoT paradigm in the healthcare domain in order to offer manifold benefits and opportunities that will considerably improve the quality of health care. The concluding chapter, **“Highly Aged and After Cloud,”** authored by Dr. Shigeki Sugiyama an Independent Researcher from Japan, presents research on the latest technological solutions in managing the most effective and proper treatment of highly aged people in Japan. The final chapter of this section, **“Gene Editing Technology and Ethical Issues,”** authored by Ms. Barbara Holland from the Brooklyn Public Library, United States, reviews gene editing technology and its study and treatment of human diseases, as well as its ethical concerns.

In summary, the primary research contents included in this reference publication is aimed to provide a much better understanding of the issues, trends, and solutions surrounding the themes of its sixteen sections, providing the coverage of the most recent research conducted by many researchers from all over the world. Collectively, the authors of the contents of this encyclopedia bring about the most current thoughtful and comprehensive overview of many important topics related to the field of information science and technology and its continuous impact on all facets of the world we are living in. We hope that their diverse and comprehensive coverage offered within their chapters will contribute to a broader awareness of all topics, research, discoveries, and solutions related to information science and technology. We are also hopeful that the contents of this publication will inspire other researchers to further explore the expansion of existing research to discover new boundaries and opportunities in the field that can be further developed to better serve the inhabitants of our planet.

Acknowledgment

Editing and completing an authoritative and comprehensive scholarly research publication such as the *Encyclopedia of Information Science and Technology, Fifth Edition* requires tremendous contributions and a great deal of assistance from large groups of scholars and staff. The primary objective of this encyclopedia is to provide the most up-to-date scholarly coverage of all topics related to the evolving nature of information science and technology, and to carry on the tradition of the four editions that successfully preceded this one.

The contributed chapters from expert researchers from all over the world provide an in-depth look into topics such as computational science, digital terrorism, cyber security and data protection, digital and wireless communications, environmental science and technologies, ethics and social responsibility, human aspects of technology, library science, medical technologies, and much more. I am indebted to all the authors for their excellent contributions to this edition of the *Encyclopedia of Information Science and Technology, Fifth Edition*.

All submitted chapter manuscripts to this publication underwent a double-blind peer review process in order to achieve the highest level of validity, reliability, accuracy, and quality of the submitted research. I am thankful to all the reviewers of this encyclopedia for providing their expertise and their rigorous, unbiased assessment of the chapter manuscripts assigned to them on a double-blind basis, as well as the members of the Editorial Advisory Board for their wisdom, guidance, and assistance with various decisions throughout the editorial process.

I would also like to convey my deepest appreciation and gratitude to all those individuals who assisted me in editing this publication, which include Lindsay Wertman, Managing Director of IGI Global, Jan Travers, Director of Intellectual Property and Contracts at IGI Global, Melissa Wagner, Managing Editor of Acquisitions at IGI Global, Maria Rohde, Assistant Development Editor at IGI Global, Crystal Moyer, Assistant Development Editor at IGI Global, Eric Whalen, Assistant Development Editor at IGI Global, Josh Christ, Assistant Development Editor at IGI Global, Chris Shearer, Copy Editing Manager at IGI Global, and Michael Brehm, Managing Editor of Book and Journal Production at IGI Global. Additionally, I would like to thank the IGI Global Sales and Marketing Department, especially Nick Newcomer, Senior Director of Marketing and Sales at IGI Global, Caroline Campbell, Marketing Manager at IGI Global, Brittany Haynes, Marketing Editorial Assistant at IGI Global, and Tori Parks, Graphic Design Coordinator at IGI Global, for their endless support in promoting this invaluable reference source.

Thanks to everyone who has provided me immeasurable amounts of knowledge, wisdom, and support over the last 30 years.

Autonomous Vehicles

Bar-Ilan University, Israel

INTRODUCTION

The first car was invented in 1870 by Siegfried Marcus (Guarnieri, 2011). Actually it was just a wagon with an engine but without a steering wheel and without brakes. Instead, it was controlled by the legs of the driver.

Converting traditional vehicles into autonomous vehicles was not just one step. The first step was just 28 years after the invention of cars that is to say 1898. This step's concept was moving a vehicle by a remote controller (Nikola, 1898). Since this first step and as computers have been becoming advanced and sophisticated, many functions of modern vehicles have been converted to be entirely automatic with no need of even remote controlling.

Changing gears was one of the first actions that could be done automatically without an involvement of the driver (Anthony, 1908), so such cars got the title of “automatic cars”; however, nowadays there are vehicles that can completely travel by themselves although they are not yet allowed to travel on public roads in most of the world. Such vehicles are called “autonomous vehicles” or “driverless cars”.

BACKGROUND

Autonomous vehicles will noticeably change the worldwide transport market. Autonomous vehicles will improve our quality of life and road safety. The number of traffic accidents will be significantly reduced. In Addition, autonomous vehicles can improve on the parking issues like the ability to park in a remote location in a rural fringe of the city. These vehicles will be more fuel efficient and their insurance will be cheaper. Also, people with disabilities can greatly benefit from this technology and military autonomous vehicles can prevent injuries and deaths in combat.

There are many practical obstacles and law difficulties that should be discussed. There were several car accidents where autonomous vehicles were involved (Wiseman & Grinberg, 2016a), (Wiseman & Grinberg, 2016b), (Wiseman & Grinberg, 2016c), (Wiseman & Grinberg, 2018). Until now two of these accidents were very tragic resulting in the death of a person.

There are several companies along with several government branches (especially military branches) that develop autonomous vehicles. Many of their products will be available for use in the coming years.

There is a need for more research until a car will be able to safely take us to our destination, without being involved in an accident and without having to drive or be there at all. Where is our car on the scale of autonomy and advanced safety? The international automotive organization SAE International (Society of Automotive Engineers) has defined six different levels of autonomous driving, or independent, in vehicles (SAE, 2014). This scale is quite acceptable in the autonomous vehicle industry. These six levels are divided into two groups: The three low levels require the driver to be active at least in part. In

DOI: 10.4018/978-1-7998-3479-3.ch001

the high three levels, there may be situations where the driver is not required to drive at all. These six levels are listed herein below:

Level 0: No Driving Automation. The driver is in charge of all driving activities in other words a vehicle which is not autonomic at all.

Level 1: Driver Assistance. One autonomic system is operating in the vehicle. For example, Electronic Stability Control (ESC) (Lie, Tingvall, Krafft & Kullgren, 2006), Adaptive Cruise Control (ACC) (Van Arem, Van Driel & Visser, 2006), Emergency Brake Assist (EBA) (Page, Foret-Bruno & Cuny, 2005). The autonomic system acts by itself as a help for the driver. However, the autonomic system is not used for driving, but only helps the driver when necessary, as an emergency device.

Level 2: Partial Driving Automation. A vehicle in which two or more autonomic systems work together, capable of simultaneously handling two tasks. For example both steers the vehicle and operate the braking system. The main limitation of this level is that in any given moment, the driver must analyze the conditions of the road and respond accordingly. Thus, even if the car is of level 2, the technology still needs the driver to be aware of the circumstances and to respond immediately to any scenario because the autonomic system cannot prevent some of the potential accidents.

Level 3: Conditional Driving Automation. In some conditions the driver is not required to monitor the driving; however, there are limitations in this level; in other words the car cannot be driven without human intervention under any conditions. For example it can be automatically driven only on highways. Accordingly, when the vehicle goes, a human driver must supervisor it, because if emergency circumstances come about, the human driver will intervene so as to avoid any potential accident if the car cannot handle the circumstances.

Level 4: High Driving Automation. The vehicle will be able under certain circumstances to operate fully autonomously and to protect its passengers from accidents. An autonomous vehicle at this level does not require a human driver to be ready to respond in an emergency, but only if the defined circumstances are kept.

Level 5: Full Driving Automation. There is no restriction to certain circumstances, nor is there a need for a human driver for supervision in emergency circumstances.

MOTIVATION

Approximately 94-95 percent of road accidents are caused by human errors (NHTSA, 2015), (Freeman, 2016). These errors are usually taken place because of smartphone use, fatigue or distraction because of any other reason (Kaplan, Guvensan, Yavuz & Karalurt, 2015). An autonomous vehicle will prevent the vast majority of them. In addition, an autonomous vehicle will always conduct itself as it has been programmed. Therefore, if a programming failure is detected that has not been occurred in all tests, it will be possible to issue an update how to correct this failure. This update will instruct all autonomous cars how to conduct themselves in a similar case (Koopman & Wagner, 2016). In this way, every autonomous car will be trained by the experience of all autonomous cars as opposed to a human driver trained only by his own experience.

Autonomous cars will be of great help for people with disabilities (Bradshaw-Martin, & Easton, 2014). For example, people with severe visual impairments can safely travel in an autonomous car. In addition, people with an exhausting job or drunk people will be able to travel in such a car without driving. Moreover, autonomous vehicles will release also people in good physical shape from the burden

of driving and will let them do other activities during their travels like work, rest or just enjoy the view (Litman, 2017).

Another issue is air pollution which will be moderated as well. Such smart junctions, whose traffic is routed on the basis of allocation of slots to pass the junction, will significantly reduce traffic jams and other delays (Fayazi, 2017). Such junctions are expected to have an important impact on the road system of each city. The travel and waiting times will be considerably shorter (Zohdy, Kamalanathsharma & Rakha, 2012). Fuel consumption will be decreased and the traffic will flow more freely, with less stoppings and accelerations, which will significantly reduce air pollution (Talebpour & Mahmassani, 2016). In addition, autonomous vehicles will be driven in a more conservative manner; therefore autonomous vehicles will consume substantially less gas and energy while travelling, compared to a traditional vehicle driven by a human, because a substantial amount of gas is consumed when driving at speed that is too high for the vehicle, accelerating excessively or unnecessary braking. Autonomous vehicles will eliminate these undesirable ways of driving; meaning less gas is consumed resulting in less air pollution.

Autonomous vehicles will put an end to the bother of hectic parking systems (Wiseman, 2017a), (Wiseman, 2017b). Furthermore, autonomous vehicles will change the land uses in the metropolitan areas anywhere (Brett, 2016). Many large parking lots will be shifted into alternative uses. (Shoup, 1997) argues that nearly a third of the central area in major cities in the US is reserved for parking. Autonomous vehicles can improve on the parking problems because of several main value-added aspects:

- Unlike traditional vehicles, autonomous vehicle will be able to drop off passengers in almost any spot in any city and then instead of cruising for a free parking (Inci, 2015), the autonomous vehicle will park itself in a remote parking lot in a rural fringe of the city where low-cost land is more readily available (Tayade & Patil, 2016); therefore there will be no necessity, for instance, for an enormous parking lot near airports as opposed to the situation that exists nowadays.
- An autonomous vehicle can park itself in a tighter fitting parking slot without scrapping nearby vehicles (Grinberg & Wiseman, 2013), (Grinberg & Wiseman, 2007). In (Bertoncello & Wee, 2015), it has been estimated that the size of a typical parking lot can be reduced by 15% because of the tighter fitting parking slots of autonomous vehicles. Therefore, autonomous cars will enable to build the parking lots in a more compact manner.
- An autonomous vehicle will be parked by the computer software (Filatov & Serykh, 2016); therefore, there will be no more occurrences of drivers parking their vehicles in an angle in a perpendicular parking; nor will there be drivers parking their cars in other ways that occupy more than one parking slot. In addition, the parking slots will be allocated according to the vehicle size and as a result the parking slots will not be any longer at the size of the largest potential vehicle (Li & Shao, 2015).

SOLUTIONS AND RECOMMENDATIONS

Traffic lights were invented at 1868 (Wang, 2016) and they have been turning out to be more sophisticated and computer controlled (Fang, 2016). The new generation of traffic lights is called “intelligent traffic lights” and it contains digital electronic units derived from common computers (Wiseman, 2016a), (Wiseman, 2016b). The traffic lights are a common sight in the streets of our cities. They use up space in the streets, need a maintenance team and consume electricity power; however, the traffic lights will probably disappear. Autonomous vehicles equipped with sensors will be able to communicate with each

other (Wiseman, Schwan & Widener, 2005). Moreover, they will be able to maintain a safe distance between them with the purpose of going across junctions without using traffic lights. Similarly to the model of air traffic control systems, computerized junctions can route traffic on the basis of time slot allocation, as a result the traffic lights can be replaced by a computerized communication system (Tachet, 2016). When an autonomous vehicle approaches a junction, an access request to the junction will automatically be sent from the autonomous vehicle to a traffic management system. This system will receive the request and assign it a unique time slot to pass the junction.

Likewise, Autonomous vehicles will be able to coordinate their way of driving, so they can move in platoon with fixed intervals (Tsugawa, Kato, & Aoki, 2011), by employing Lidar and ultrasonic range-finders (Wiseman, 2018) with the intention of distance reduction between them, without any risk of collisions. These platoons will reduce traffic congestion on roads, will increase the energy efficiency of driving and will reduce the air pollution generated by vehicles (Fernandes & Nunes, 2012).

DIFFICULTIES AND OBSTRUCTIONS

The Luddites (Jones, 2013) were a movement of English workers in the beginning of the 19th century who protested, sometimes even by violence measures like destroying machines, against the changes brought about by the Industrial Revolution, which they saw as a threat to their livelihood. Similarly, Autonomous vehicles can cause mass joblessness in the automotive industry. Professional drivers like taxi drivers or truck drivers will not be required anymore. Likewise the Luddites, some unhappy professional drivers attacked autonomous vehicles in California (Wong, 2018). This joblessness will also occur in the garage industry. When 95 percent of the vehicular accidents are eliminated, a much small number of garages will be required and a large amount of automobile mechanics will be fired and will not be able to find a new job. Significantly lower rate of vehicular accidents will also cause less damage to road infrastructure, bringing about some reduction in need for workers in the road maintenance sector.

Another issue that can be challenging is cyber criminalism or cyber terrorism (Petit, & Shladover, 2015). In the future, almost all if not entirely all the vehicles will be exclusively controlled by computers. If the software is not perfect and some flaws make the software vulnerable, smart hackers might be capable to unlawfully interfere with the vehicle software, so they will be able to harm the vehicle or even worse harm the vehicle occupants. In addition, a new version of car thefts may possibly be a fleet of autonomous vehicles thefts.

The trouble of traffic congestion is very acute in many cities and highways (Wiseman, 2017c), (Wiseman, 2017d), (Wiseman, 2017e). The autonomous vehicles will add many cars to the already congested roads, because of several reasons:

- Children are a significant portion of the world population; however, they mostly do not own a vehicle; nor do they drive a vehicle. When autonomous cars are available, the children will be able to own a vehicle and to “drive” vehicles. It is hard to predict which portion of the children population will use private cars instead of the public transportation (Fagnant & Kockelman, 2015), but even if a small percentage of the children are added to the already congested roads, it might augment the congestion difficulty.
- Similarly to the children, people with a disability like blindness or other severe disability that nowadays prevents them from driving a vehicle, will be able to use an autonomous vehicle by themselves. Actually, this happening was one of the first motivations for the developing of autono-

mous cars because such a car will definitely and substantially improves on the disabled quality of life (Madarasz, Heiny, Crompt & Mazur, 1986); however, this improvement will add more vehicles on roads.

- Some people prefer to travel by public transportation because they like to relax while going to their destination. Some of them want to sleep, read or just not arriving in an edgy mood after conflicts with other drivers while driving. The autonomous vehicle will give these people the opportunity to have this rest with no need of public transportation. Traveling by an autonomous vehicle will be usually even a better relaxation because there will be no need for connections i.e. to change from bus to train etc. nor will there be other people in the vehicle. This will make more people to choose the autonomous vehicles.
- More traffic will be added because empty vehicles will go alone in their way to park. Nowadays, drivers make an effort to find a close parking lot, so they will not have to walk a large distance; however, an autonomous vehicle can go by itself to a remote parking lot.

In spite of this added traffic, autonomous vehicles will drive more efficiently, so there are more than a few analyses which have confidence that this efficiently way of driving can counterbalance the added traffic and even obtaining a better traffic flow.

FUTURE RESEARCH DIRECTIONS

The current world population is more than 7.6 billion; however it is expected to reach 10 billion in the year 2056 (Worldometers, 2018). In addition, the standard of living has been increasing in most of the world countries and it is expected that more people will be able to own a car in the coming centuries (Reich, 2010). The reasons mentioned in the previous section for potential excessive congestions when autonomous cars are available will also play a part in the even now congested roads, that is to say many current roads are already congested and even if a major road construction is performed and even a second floor is built in the most congested roads, the problem of traffic congestion will be acute. This concern of congested roads has already stimulated enterprises all over the world to make the first moves toward flying cars.

A flying car will be a private air vehicle which can travel both by air and roads. Many prototypes of such cars like AeroMobil (Becker, 2017), Urban Aeronautics' XHawk (Yoeli, 2002), The Skycar (Pecora, Pecora & Lecce, 2011), The Xplorair (Altran France, 2013) and many more (Frost & Sullivan, 2017) have been built and have been tested; however, the production of these flying cars has not yet started for a widespread use.

The concept is a vehicle that is able to fly and to vertical take-off and land (VTOL). Such a vehicle will be able to go without a road and also several levels of elevation can be attained, as a result there will be a multiple level road without a need to pave even a single mile of road.

Autonomous flying cars will also have the ability to connect and to move in platoons, so they will be able to catch sight of a much larger area, so they will be much safer and more efficient (Wang, Xu, Leng, & Pollin, 2018, June).

The overall consequences of autonomous vehicles are still unknown and the impact on other means of transportation is unclear (Wiseman, 2019a). Also, the impact on transportation infrastructure is undecided (Wiseman, 2019b). When the autonomous vehicles penetrate the transportation market, more information will be available and this information will enable more profound research.

CONCLUSION

Autonomous vehicles are self-guided vehicles that overcome obstacles without any help of a human driver. These vehicles are expected to go on the same road and with the same traffic signs we are currently familiar with. Autonomous vehicles are equipped with several apparatus that enable them to observe their surroundings and decide in real time what action should be taken.

Autonomous vehicles are expected to be safer than vehicle driven by human drivers. Furthermore, autonomous vehicles will release people from the burden of driving and will give them more time to rest, work or do other activities. These vehicles can be operated by children or other incapable persons. In addition, they will be driven in more efficient manner than an average driver. Parking concerns will be enormously affected by autonomous vehicles because autonomous vehicles can park themselves in a remote location and in a tighter fitting parking slot.

There are some concerns like many professional drivers who will lose their jobs and the potential congestions ensued by additional vehicles going empty or going with children; however with a proper preparations the shift to autonomous vehicles can be done smoothly and efficiently.

KEY TERMS AND DEFINITIONS

Absolute Positioning: A system that is able to locate the precise autonomous vehicle position, so the vehicle will be able to know where it should make its turns.

Automated Highway System (AHS): A system that is capable to drive a vehicle in a highway by itself in a pre-determined route. This system can significantly reduce distances currently necessitated

between vehicles, so as a result such systems will be able to relieve many traffic congestions. Such systems are typically combined with adaptive cruise control and collision avoidance systems and typically used by autonomous vehicles level 3 or higher.

Computer Vision: Systems that are in charge of an autonomous vehicle's ability to observe its surroundings.

Far Infrared Sensors (FIRS): Sensors employed by autonomous vehicles with the purpose of obtaining the heat outline of pedestrians or animals, so as to avoid a collision with them. These sensors can work together with traditional cameras and LIDAR, so as to decide together on the safest choice.

Intelligent Driver Assistance Systems (IDAS): Devices aiming at improving vehicle safety, for example, blind spot monitor or traffic signs recognition.

Internet of Vehicles (IoV): Internet of vehicles is a wireless network used for information exchange between vehicles, infrastructure, pedestrians using the traditional Internet protocols and networks.

Light Detection and Ranging (LIDAR): A laser-based radar used in autonomous vehicles. In nowadays autonomous vehicles, the LIDAR unit is typically located on the vehicle roof with the aim of enabling unimpeded 360-degree view of the autonomous vehicle surroundings.

Platooning: Multiple autonomous vehicles that communicate and exchange information in order to move and maneuver simultaneously. Commonly the vehicles go in a convoy, so as to increase road capacity.

Vehicle to Infrastructure (V2I): Communication technology enabling information exchange between vehicles and infrastructures.

Vehicle-to-Vehicle (V2V) Communication: Communication technology enabling information exchange between vehicles.

Convolutional Neural Network

INTRODUCTION

In a broad sense, a convolutional neural network is one of many methods to achieve artificial intelligence.

Artificial intelligence (AI) is a field of computer science dedicated to the research of methods and algorithms that permit to perceive information from the environment, learn from it and taking actions and decisions based on the learning outcomes without any explicit orientation from external agents. AI consists of many sub-fields, including evolutionary computation (e.g., genetic algorithms), vision (e.g. object recognition), expert systems (e.g. decision support systems), speech processing (e.g. speech recognition), natural language processing (e.g., machine translation), and machine learning (e.g. decision trees).

Machine learning (ML) is a type of algorithms and models for computing systems to do tasks based on pattern identification and inference (Mitchell, T., 2017). When it is difficult or infeasible to develop an algorithm to do a particular task, machine learning algorithms can provide an output based on previous data. Machine learning algorithms identify features from data and build models from these features so that new decisions can be produced based on these models and rules. Examples of machine learning models include deep learning, support vector machines (SVM), genetic algorithms, clustering, dimensionality reduction, artificial neural network, decision tree and others.

In this chapter we are particularly interested in deep learning (DL) (Aggarwal, C., 2018). Deep learning teach computers to learn by example. Deep learning first appeared in 1980, but only recently has been applied in practice because it requires large amounts of labeled data and high-performance computing. Its application is vast including areas like computer vision, speech recognition, language processing, among others.

The most recent deep learning models are based on artificial neural networks (ANN) with a large number of layers. Deep learning networks are first trained using a large set of labeled data in order to learn features from the training data without being explicitly programmed to learn them.

There are several types of artificial neural networks including the feedforward neural network, the Kohonen self organizing neural network, the recurrent neural network, the convolutional neural network, the modular neural network, among others. The convolutional neural network (CNN) is one of the most used deep learning architecture for artificial intelligence (see Figure 1).

Convolutional neural networks are one of the most used deep learning models in the industry and business. Therefore, for those interested in understanding how deep learning is applied in this markets it is fundamental to understand the architecture of CNNs and understand the evolution and trends of CNNs during the last decade.

This article focus on convolutional neural networks with a description of the model, the training and inference processes and its applicability. It will also give an overview of the most used CNN models and what to expect from the next generation of CNN models.

Figure 1. Convolutional Neural Networks in the context of artificial intelligence

BACKGROUND

Artificial neural network (ANN) is a machine learning model that mimics the structure of the human brain consisting of interconnected neurons. Theoretically, an ANN is a universal model capable to learn any function (Hornik et al., 1989). A class of ANN is the convolutional neural network introduced in (LeCun, Y. et al., 1989).

Convolutional neural networks process images. The network applies successive convolutions to the input image using several trained filters to identify features of the image. Features identified in a convolution are processed by the next convolutions to identify more complex features. The process permits to learn complex features and at the same time is invariant to translation of the features.

Artificial Neural Network

An artificial neural network consists of input, output and hidden layers, which are all layers between the input and the output layers (see Figure 2).

Figure 2. Artificial Neural Network

Each layer contains nodes or neurons that map all its inputs into an output to be used by the nodes of the next layer. Nodes of a layer are connected to the nodes of the next layer, except the output layer whose outputs are the result of the neural network. The first layer – input layer – generates the inputs of the first hidden layer and the output layer receives the inputs from the last hidden layer and produces the classification result. A neural network with more than three hidden layers is designated deep neural network (Bengio, Y., 2009).

A layer can have any number of neurons. The input layer has many neurons as the number of input data, while the number of neurons in the output layer depends on the target application. For example, in a neural network used to classify images, the number of output neurons is the number of classification classes of the network.

Neuron Function

Let's consider a neuron with n inputs from n neurons of the previous layer, $\{x_1, x_2, x_3, \dots, x_n\}$. Each connection between neurons has a weight, $\{w_1, w_2, w_3, \dots, w_n\}$ (see Figure 3).

Figure 3. Neuron function

The output of a neuron, y , is computed as follows:

$$y = f\left(w_0 + \sum_{k=1}^n w_k x_k\right)$$

Weight w_0 is in fact an external input called bias introduced in the graph with a unitary neuron. Function $f(\cdot)$ is called an activation function and is used to decide the output of the neuron. Activation functions can be linear or non-linear and are chosen according the domain of application (Nwankpa, C. et al, 2018).

A simple activation function is the Heaviside function that is 0 for negative values and 1 for the others. However, piecewise-linear functions are not differentiable and training requires differentiable func-

tions. A well-known used activation function is the sigmoid given by $\frac{1}{1+e^{-z}}$. It is usually used to predict a probability since it varies between 0 and 1. For multiclass classification, the softmax function is used. This function takes as input a vector of k values and normalizes it into a probability distribution of k probabilities.

Another used activation function is the hyperbolic tangent that varies between -1 and 1, increasing the output range.

The most used activation function is now ReLU (Rectified Linear Unit). The function is 0 when the input is negative and is equal to the input when the input is positive. The function is not differentiable at 0, so it is assumed that the derivate at zero is zero because it gives better results than assuming one.

Training Neural Networks

Training is the process of determining all weights of the network so the outputs of the network give the best mapping results. The training can be supervised or unsupervised. In supervised training, the network knows the output for each input. Unsupervised training is when the network has a training set without the desired outputs. In this case, the network has to find some features of the input data to classify them.

In the supervised training all weights, $Wset$, are adjusted to minimize an objective function that quantifies the error, E , between the M outputs, y_k , and the desired outputs, t_k , for all N data inputs, x_n . Usually, the error is calculated as the sum of squared error:

$$E(Wset) = \sum_{n=1}^N \sum_{m=1}^M (y_k(x_n, Wset) - t_k)^2$$

Training a neural network is an iterative process of two main steps: forward propagation and back-propagation. The first step is to enter an input data and propagate it through the whole network to find the prediction value with a set of weights. Next, a loss function (sum of squared error) is applied to determine the error between the observed output and the expected output. In the ideal case, the loss should be zero, meaning that there is no difference between the observed and the expected values. The loss value is then propagated backwards to all neurons that are in a path from the inputs to the output. Each neuron receives a fraction of the loss according to its contribution to the output. So, neurons with a higher contribution to a particular output will receive a higher fraction of the loss function associated with that output. After all neurons receive the loss fraction, weights are adjusted to reduce the loss. Weights are changed using a technique designated *gradient descent*. According to this technique, weights are changed in small increments based on the derivative of the loss function, that is:

$$\Delta W[i] = -\gamma \left(\frac{\partial E_n}{\partial w[i]} \right)$$

where γ is the learning rate.

Weight initialization is important in the final quality of the trained network. Some works indicate that better results are obtained when the weights are randomly chosen between specific normalized ranges (Glorot, X. & Bengio, Y., 2010).

In the unsupervised training, given a training set without expected outputs, the method has to train the network based on characteristics of the input data. One known method for unsupervised training is the auto-encoders. This technique is similar to a compression algorithm that uses a smaller subset of features to represent the input data (Bengio, Y., 2009).

Convolutional Neural Network

A traditional neural network can be applied to images. However, even with images of medium size, the number of input neurons is high and consequently there would be a high number of weights from the input neurons to the first hidden layer. For example, considering an image of size 224×224 , there are over 50000 input nodes. With the same nodes in the second layer, we would need 50000×50000 weights just for the first layer. This number of weights is very difficult to train with good results and needs a huge amount a memory and computational effort. A better approach is to take into consideration the type of input data, an image in this case (LeCun, Y., 1989). Convolutional neural networks consider the spatial information between pixels, that is, the output of a neuron of the input layer is the result of the convolution between a small subset of the image and a kernel of weights.

A regular convolutional neural network has different types of layers: convolutional, pooling and fully connected. CNN may have other particular layers different from these and are known as irregular CNN. In the following, we explain in more detailed the three types of regular layers.

The **convolutional layer** receives a set of input feature maps (IFM) and generates a set of output feature maps (OFM). A feature map is a 2D matrix of neurons and several feature maps form a 3D volume of feature maps (see Figure 4).

Figure 4. Input and output feature maps of a convolutional layer

A 3D block of weights – kernel or filter – is convolved across the width and the weight of the input feature maps and computes the dot product between the kernel and the feature maps generating an output feature map. Each different kernel produces one output feature map. Therefore, the number of output feature maps is the same as the number of filters of the layer. Each kernel is trained to detect a particular feature of the input data. To explore spatial local correlation between adjacent neurons the convolution window (width $\times$ weight) of the kernel is usually small (e.g., 3×3 , 5×5 , etc.), while the depth of the kernel is the same as the number of input feature maps.

Usually, kernels slide across the feature maps shifting one neuron each time (stride of 1). This generates high overlapping that increases with the window size and output feature maps with the same size. Instead, a larger stride can be used resulting in less overlapping and a smaller output volume. Another parameter of the convolution process is the padding of the IFMs. If we run a kernel with window size 3×3 over an input feature map of size $k \times k$, the output feature map will have a size $(k-2) \times (k-2)$. In many cases, it is desirable to preserve the size of the maps. One solution consists to pad the border of the IFMs with zeros. In this case, padding the border with one level of zeros would produce output feature maps with the same size of the input feature maps.

The **pooling layer** subsamples the IFMs to achieve translation invariance and reduce over-fitting. Basically, the relative location of a feature is more important than its absolute location.

Given an input image and the pooling size (typically two or three), pooling partitions the image in 2D arrays of the size of the pooling window. Then, it applies a pooling function to all members of the pooling window (see Figure 5).

Figure 5. Input and output feature maps of a convolutional layer

Examples of pooling functions are average pooling (average between the output neurons of the window) and max pooling (maximum value between the output neurons of the window). Considering, for example, a pooling window with entries $\{2, 4, 6, 8\}$, the max pool would return 8, while average pooling returns 5. Max pooling gets faster convergence during training (Scherer, D. et al, 2010). Also, it reduces the number of weights and consequently the required memory to store them and the amount of computation. Pooling is not applied to all convolutional layers.

The size of the pooling window determines the reduction of the feature maps. The typical size of 2×2 applied with a stride of two downsamples the input maps in both dimensions reducing the original map 75%. Note that pooling reduces the size of the map but the number of feature maps remains the same.

The last layers of a convolutional network are **fully connected**. A fully connected layer follows the structure of the traditional neural network where all neurons of the layer are connected to all neurons of the previous layer. Algorithmically, it is a vector-matrix multiplication followed by vector addition of the bias values.

To better understand the concepts introduced, let's consider the first convolutional neural network to achieve high accuracy for hand digit classification LeNet (LeCun, Y. et al., 1995). LeNet has two sets of convolutional and average pooling layers, followed by a flattening convolutional layer, two fully connected layers and a softmax classifier. The activation function is the hyperbolic tangent (see Figure 6).

The input of LeNet is a grayscale image of size 32×32 . The first convolutional layer uses six filters with a window size of 5×5 and a stride of one producing six output feature maps of size 28×28 , since it does not consider padding. Then it is applied an average pooling layer with a filter of size 2×2 and a stride of two, reducing the feature maps to 14×14 . A second convolutional layer is applied with sixteen

Figure 6. Architecture of LeNet

filters of size 5×5 and stride of one generating sixteen output feature maps of size 10×10 which are then pooled to size 5×5 . The next layer is a convolutional layer with 120 feature maps of size 1×1 . Then comes one fully connected layer with 84 units followed another fully connected layer with ten outputs, one for each digit and the softmax classifier.

Recent Convolutional Neural Networks

CNNs have many parameters to be defined, like the number of layers, the number of neurons, the size of filters, the size of pooling, the activation function, the learning rate, more and new type of layers, among others. The exploration of design space defined by all these parameters lead to many proposals of CNN. In the following, some of the most known CNN for its results and novelty will be described.

LeNet

LeNet (LeCun, Y. *et al.*, 1995) was able to demonstrate some robustness features of CNN to rotation, distortion, scale, etc. In total, the network has 60K parameters or weights and an accuracy above 99% (see architecture in Figure 5, in the previous subsection).

AlexNet

The next big step of CNN application was achieved with AlexNet (Krizhevsky, A., 2012) considered the first CNN with great results for image classification. AlexNet is a deeper network than LeNet and 60 M parameters, 1000× more parameters than LeNet. AlexNet has five convolutional layers, three pooling layers after convolutional layers two, three and five, and three fully connected layers. Instead of the hyperbolic tangent, the activation function of AlexNet was ReLU to improve the convergence rate of learning and the problem of vanishing gradient (Hochreiter, S., 1998). The input images have size $227 \times 227 \times 3$ and the network uses larger filter sizes in in the first (11×11) and second layers (5×5).

AlexNet won the 2012 ILSVRC (ImageNet Large-Scale Visual Recognition Challenge) with a top-5 error rate of 17.0% (top-5 is the error rate at which given an image the network does not include the correct label within its top five predictions) and a top-1 error rate of 37.5% with ImageNet (Imagenet is a large database of images for use in object recognition research. It has over 15 million annotated images with more than 22000 categories).

ZefNet

Until 2013, the design of a CNN was based on trial and error, changing the parameters without a clear understand of what was happening in the CNN layers. In 2013 a multiplayer deconvolutional neural network was proposed in (Zeiler, M. D. & Fergus, R., 2013) named ZefNet. Instead of just proposing a new CNN, the authors also proposed a technique to observe the network activity of AlexNet (can be applied to other networks) named Deconvolutional Network, which monitors the output of neurons to establish correlations between features and input neurons. The idea has already been explored with Deep Belief Networks (Erhan, D., 2009) and Autoencoders (Le, Q. V., 2013).

When applied to AlexNet the method have shown that only a few neurons were active in the first two convolutional layers. Based on these observations, the authors have fine tuned AlexNet achieving a top-5 error rate of 11.2%. A few more modifications in both the model and the training process were considered. For the training process, they considered only 1.3 million images, but even so it took twelve days to train the network. They substituted the filter of the first convolutional layer (size 11×11) by a filter of size 7×7 to retain more information from the image.

VGG

In 2014 the VGG neural network brought some new directions to CNN development. They considered two main foundations for the development of VGG, simplicity and uniformity of layers and depth of the network. Six different architectures were tested and the one with best accuracy was VGG-16 with sixteen layers using only 3×3 filters with stride and pad of 1, and 2×2 pooling with stride 2. The authors concluded that two convolutional layers with 3×3 filters has the same results of a single layer with 5×5 filters. The same for three 3×3 filters instead of a single 7×7 filter. This reduces the number of parameters and applies the activation function more times. Another option in the design of VGG was to increase the number of filters after each pooling step as we move to the next layers. So, the size of the feature maps decrease but the depth increases as we move along the network.

Like the previous architectures it was trained with batch gradient descent and the training took from two to three weeks with four GPUs. VGG did not win the ImageNet contest that year but improved previous year top-5 error rate to 7.3%. The main drawback of VGG is that it has 138 million parameters, the main reason for its long training times.

GoogleNet

The winner of the ILSVRC in 2014 was GoogleNet (Szegedy, C. *et al.*, 2014), also known as Inception-V1. Previous CNNs followed a regular approach of stacking convolutional, pooling and fully connected layers with variations in the number of layers, and number and size of filters. GoogleNet broke this regular structure. The layers of a regular CNN are serialized with one after the other. In GoogleNet groups of convolutions run in parallel defining a module named Inception (see Figure 7).

In the inception module, there are four main operations in parallel, namely three convolutions with different sizes (1×1 , 3×3 , 5×5) and one 3×3 max pooling. To reduce the number of operations, the 3×3 and 5×5 convolutions are preceded by 1×1 convolutions to reduce the volume of data.

The inception module is like a small network inside a larger network that is able to extract information at different scales with different window sizes. The pooling operation reduces the size of output data.

Figure 7. Inception module of GoogleNet

The complete GoogleNet network has nine inception modules and does not use fully connected layers. Instead, an average pool is used after the last inception that reduces the output $7 \times 7 \times 1024$ volume of the last inception module to a $1 \times 1 \times 1024$ volume.

GoogleNet uses 6.8 million parameters to achieve a top-5 error rate of 6.7% for ImageNet.

Other versions of the inception module have followed. Inception-v2 and inception-v3 were presented in the same paper (Szegedy, C., 2016). In this work, the convolution with size 5×5 was replaced by two 3×3 convolutions. They factorize convolutions of size $n \times n$ to a combination of two filters $1 \times n$ and $n \times 1$ applied in parallel. Inception-v4 introduced some more modifications and optimizations. Modules were made more uniform and the complexity was reduced. In spite of uniformization, they created three different inception modules.

ResNet

ResNet (He, K., et al., 2015) has increased the number of layers to 152 and won the ILSVRC competition in 2015 with a top-5 error rate of 3.6% (human error for image classification is from 5 to 10%). ResNet not only pushed the depth of the network but have also introduced a new block named *Residual Block* (see Figure 8).

Figure 8. Residual Block of ResNet

In the residual block the result a series of two convolutional layers is added to the input of the residual block. So, instead of just processing the original input with a series of convolutional layers, the result of the convolutions is added to the original input, like a delta factor. According to the paper, the new structure permits a better optimization of the network.

Similar to what happened in VGG, ResNet increases the layers and decreases the size of maps very soon. After the first two layers maps are reduce to one quarter of the original image size.

ResNeXt

ResNeXt (Xie, S., et al., 2017) is the follower network of ResNet with slightly better results than the original ResNet with a top-5 error of 3.03%. The model introduces the concept of cardinality that splits the original residual block without increasing the complexity (see Figure 9).

Figure 9. Residual block with cardinality

On the left, we have an example of a residual block with two convolutions and on the right we have a cardinality block that splits the original residual block in 32 blocks (the cardinality of the block). The complexity is the same since the set of filters is also split across each member of the cardinality block.

DenseNet

DenseNet (Huang, G., 2018) is a CNN architecture also based on ResNet with some modifications in the residual block. The work proposes the *Dense Block* to replace the residual block. The dense block has several layers, but instead of receiving data only from the previous layer it receives data from all preceding layers and sends the output to all subsequent layers within the block. Instead of addition, the block uses concatenation to group data from previous blocks.

The structure has some advantages over ResNet. During training the backward error propagation reaches earlier layers with a straight path. The number of parameters in DenseNet is smaller than in ResNet (about half for the same number of layers). Receiving information from several previous layers increases the diversity of features processed by a single layer. The accuracy of DenseNet is close to the one achieved with ResNet but with less parameters.

SENet

SENet (Hu, J., Shen, L., Sun, G., 2018) introduced a new network block – squeeze-and-excitation. The idea of the block is to emphasize important features and cancel less useful ones. The block runs the convolutions of the residual block of ResNet. Each feature map is then squeezed to a single value using a global average pooling. Next, a fully connected layer followed by ReLU is applied to introduce non-linearity. A second fully connected layer is applied followed by a sigmoid activation function. The result is finally added to the original input, like in the residual block.

With these modifications, SENet won the ILSVRC competition in 2017 with a top-5 error rate of 2.25%.

Application Examples of Convolutional Neural Networks

The set of target applications of convolutional neural networks is growing. Since these networks are dedicated to image analysis, any application associated with image and video is a potential candidate for this type of deep neural networks. Face recognition (Kalinowski, I., & Spitsyn, V., 2015) and scene labelling (Pinheiro, P. & Collobert, R., 2014) already applies successfully a CNN. Face recognition with a CNN identifies faces in an image and match each face to a name from a database. The advantage of the CNN model compared to other machine algorithms is its high accuracy independent of external factors, such as light or view angle. Face recognition is applied in social networks, like Facebook, entertainment applications that change the aspect of the face, surveillance cameras, among others.

Other type of image recognition is the process of identifying written characters of symbols from an image. Image tagging is also using CNNs. eCommerce platforms are using these applications to match the images accessed by users to their commercial needs.

Medical image analysis is another hot area that is starting using CNNs to analyze medical images (Razzak M.I., 2018). Images associated with many types of exams are classified with a CNN with an accuracy higher than that obtained by the human. With the vast amount of medical information available, there is enough data for CNNs to analyze medical images with high success. Medicine applications are not just image analysis. Health risk assessment is another application area, where CNNs are used to analyze the past data of a patient and determine the probability of occurrence of certain diseases, propose the best way to treat it or even explore the risks for people close to the patient.

Autonomous driving is another hot topic for convolutional neural networks (Kocic, J., 2019). The system receives images from cameras attached to the vehicle and determines the driving direction of the vehicle. The task is complex since the vehicle has to take into consideration many other aspects, like traffic sign recognition, detection of persons in the street, etc.

Convolutional neural networks are applied in many other machine learning applications. The list is already vast, including code generation (Pengcheng, Y. & Neubig, G., 2017), analysis of sentiments (Lei, T., Barziley, R. & Jaakkola, T., 2016), image segmentation (He, K., et al., 2017), text recognition (Jaderberg, M., et al., 2016) and object recognition (Redmon, J., & Farhadi, A., 2017), just to name a few.

FUTURE RESEARCH DIRECTIONS

Many CNN models are proposed every year and the accuracies are increasing with each network. Initial CNN were regular structures based on convolutional, pooling and fully connected layers. The accuracy

of CNN was then improved with the introduction of new layers. These irregular structures have improved the training and inference of CNN at the cost of some specificity of particular layers.

In spite of all the evolution, the study and development of CNNs are still in its infancy and new challenges are yet to be resolved. Some of these challenges are associated with training. CNN are very good on classifying good images but are still little robust to image distortions and noise. Another problem is that it is difficult to understand and verify what is going inside the layers and the influence of each filter or layer over the network results. Another major challenge is that CNNs require large amounts of data to learn. So, those applications with few training images are difficult to be modeled with a CNN. Training a CNN is a hard processing task that requires high-performance computing platforms. Inference is less demanding but still requires high computing power. How to do inference and training in edge devices with low computing resources is an actual area of intense research.

CNN still continue to evolve and new achievements are expected in the near future. A recent training issue is how to incrementally train an already trained network. A running CNN can keep learning with new data to improve its classification capability. The question is how to incrementally change the network without retraining the network for all input data set.

The time needed to train a network is a major concern since it limits the continuous increase of network complexity. Also, the inference in edge devices with low resources also limits the network complexity. Two paths have been followed to overcome this embedded limitations. One way is to improve hardware computing power and apply network optimizations to reduce complexity. Another way is to design networks for embedded devices (Sandler, M.B., 2018). So, CNN development cannot be independent of the target hardware.

Many parameters have to be determined in a large CNN. Many of these, like size and number of filters, are explored manually. Some automatic algorithms can be used to explore the design space but it takes a long time. So, it is important to clearly understand the relation between each type of parameters and the network accuracy so that the design process can be faster.

CONCLUSION

The article describes the fundamentals of convolutional neural networks, the most known types of layers and CNNs proposed in the literature. Since the first successful CNN for character recognition, followed by AlexNet for image classification that many new networks have been proposed with better accuracies. Networks with more layers, new types of layers, new optimization techniques to help the accuracy and improve training have helped to evolution of CNN.

Researchers have been concerned about understanding the internals and mechanisms of CNN so that new improvements have some reasoning and are not just based on an empirical process of trial-and-error. Another concern is about the complexity of the networks and the computing requirements. In a near future it is expected an increase of CNNs running in edge devices. This requires an extra care over the development of CNN since they have to run in a constrained computing platform.

Therefore, in spite of 20 years of research and development, CNNs are still an actual topic of intense research.

KEY TERMS AND DEFINITIONS

Activation Function: The activation function defines the output of a neuron given a set of inputs from the previous layer or data input.

Artificial Neural Network (ANN): It is a computing model based on the structure of the human brain with many interconnected processing nodes that model input-output relationships. The model is organized in layers of nodes that interconnect to each other.

Convolutional Layer: A network layer that applies a series of convolutions to a block of input feature maps.

Convolutional Neural Network (CNN): A class of deep neural networks applied to image processing where some of the layers apply convolutions to input data.

Deep Learning (DL): A class of machine learning algorithms for automation of predictive analytics.

Deep Neural Network (DNN): An artificial neural network with multiple hidden layers.

Feature Map: A feature map is a 2D matrix of neurons. A convolutional layer receives a block of input feature maps and generates a block of output feature maps.

Fully Connected Layer: A network layer where all neurons of the layer are connected to all neurons of the previous layer.

Network Layer: A set of neurons that define the network of a CNN. Neurons in a network layer are connected to the previous and to the next layer.

Pooling Layer: A network layer that determines the average pooling or max pooling of a window of neurons. The pooling layer subsamples the input feature maps to achieve translation invariance and reduce over-fitting.

Softmax Function: A function that takes as input a vector of k values and normalizes it into a probability distribution of k probabilities.

Supervised Training: A training process of neural networks where the outcome for each input is known.

Unsupervised Training: A training process of neural networks where the training set does not have the associated outputs.

Human-Agent-Robot Teamwork (HART) Over FiWi-Based Tactile Internet Infrastructures

INTRODUCTION

In the current digital Darwinism era, technologies are evolving faster than the business organization can naturally adapt (Daugherty, 2018). In the past, business executives focused on using machines to automate specific workflow processes. Traditionally, these processes are linear, stepwise, sequential, and repeatable. But performance gains from that traditional approach have recently been leveling off, as companies wring the last bits of efficiencies from mechanistic automation. The traditional approach (either human-only activity or machine-only activity) has been to view humans and machines as rivals, each side fighting for the other's job. The truth is that companies can achieve significant boosts in performance, when machines and humans work together as allies, not adversaries, to capitalize on each other's complementary strengths. For instance, performing routine tasks and detecting hidden patterns in an image can be easy for machines, whereas dealing with unsatisfied customers can be easy for humans. To achieve higher productivity gains than traditional systems, currently leading firms in many industries are re-imagining their business processes to be more flexible, faster, and adaptable to customer behavior, preferences, and needs of their workers in a given moment. This trend of exploiting the adaptive system for symbiotic collaboration between humans and machines is unlocking what is known as the third wave of business process transformation. This collaboration allows weak workers to transfer tedious tasks to powerful machines and by enabling them to perform their work faster and more efficiently through expert guidance, advice, and support from artificial intelligence (AI) based systems. Hence, to realize beneficial human-machine coactivity in different business processes, the fundamental question that naturally arises is how to enable real-time collaboration and communication between humans and machines. To answer this question, some of the key technological terms are described below in greater detail:

To unleash the full potential of many real-time cyber-physical systems (CPSs) that harness human-machine interaction, including virtual and augmented reality, an extremely low round-trip latency of 1-10 milliseconds is required to match human interaction with the environment. This vision of ultra-low latency communications gives rise to the so-called *Tactile Internet*, which has recently emerged to steer/control virtual and physical objects (e.g., remote-controlled robots) and to transmit touch and actuation in real-time (Maier, 2016). Key Tactile Internet applications include real-time gaming, wireless controlled exoskeletons, remote surgery, elderly/disabled people care, driver-assistance systems to support humans in arriving safely and comfortably at their destinations. By enabling ultra-low latency communications between humans and machines in conjunction with carrier-grade robustness and availability, the Tactile

DOI: 10.4018/978-1-7998-3479-3.ch003

Internet represents a paradigm shift from traditional wired and mobile Internet based content-delivery to labor-delivery networks via tactile/haptic devices. At the nexus of computerization, automation, and robotization lies the emerging Tactile Internet, which will be centered around human-to-machine/robot (H2M/R) communications by providing the medium for transporting haptic (i.e., touch and actuation) and non-haptic (data, video, and audio) traffic in real-time (Maier, 2018). By offering highly reliable and responsive network connectivity for real-time human-machine interaction centric applications, the Tactile Internet holds great promise to have a profound socio-economic impact on our everyday life, ranging from healthcare (e.g., remote robotic surgery), transport (e.g., driver assistance system) to entertainment (e.g., online gaming) and manufacturing industry. The long-term goal of the Tactile Internet is to enable emerging products and services that complement humans rather than substitute for them. Recently, Stanford University launches its inaugural report on “*Artificial Intelligence and Life in 2030*,” in which they predicted that within next 10-15 years a vast amount of intelligent human-aware systems will be developed. Unlike the Internet of Things (IoT) without any human involvement in its underlying machine-to-machine (M2M) communications, the Tactile Internet involves the inherent human-in-the-loop (HITL) nature of haptic interaction and thus allows for a human-machine cooperative design approach towards creating and consuming novel immersive experiences via the Internet.

Recently, Garry Kasparov emphasized the need for a strong coordination process for better human-machine co-activity in his book “*Deep Thinking: Where Machine Intelligence Ends and Human Creativity Begins*,” where he shows that a strong human worker + machine worker + weak coordination process is less effective than its weak human worker+ machine worker+ strong coordination process counterpart. In other words, an intelligent process with inferior technology and inferior knowledge outperforms a less intelligent process with superior technology and knowledge. This observation of Garry Kasparov was recently also appreciated by Google and other Silicon Valley companies. In fact, leading technological companies have been putting more efforts in developing AI systems that augment human capabilities (see, e.g., IBM’s Watson) instead of replacing them with autonomous systems. According to Kasparov, this isn’t just user experience (UX), but entirely new ways of bringing human-machine coactivity into diverse fields (e.g., business process and organization management) and creating the new tools/intelligent process we need in order to do so.

A promising approach toward achieving advanced human-machine coordination by means of a superior process for fluidly orchestrating human and machine coactivity may be found in the so-called *human-agent-robot teamwork (HART)* research (Johnson, 2011). In HART, the dynamic allocation of functions and tasks between humans and machines (e.g., robots and cloud servers) is crucial, which may vary over time or be unpredictable in different situations. HART differs from the traditional humans-are-better-at/machines-are-better-at (HABA/MABA) approach, which only allows human-only activity/machine-only activity without driving any symbiotic human-machine development in search for synergies (Bradshaw, 2012). Conversely, with a HART-centric Tactile Internet design approach, humans, collaborative robots, remote cloud, and decentralized cloudlet resources together acting as an intelligent multi-agent system exploit the different characteristics of requested tasks and jointly execute them by using smart orchestration techniques. Considering the underlying human-machine interaction in HART-centric Tactile Internet applications, the main challenge is to orchestrate how tasks can be best shared in concert. Collaboration and communication among HART members are essential to cope with dynamic changes in the task environment, thereby improving the task execution latency. Note that depending on location awareness, a HART task can be either a location oriented physical task (e.g., sensing at a given task location, moving and carrying products to another location), a location independent cognitive task (e.g., caching or object recognition, which might be offloaded for computation onto a powerful cloud server/agent

for processing), or may include both location dependent and independent tasks (e.g., sensing at a task location, sensed object recognition, and cached content delivery of the sensed object). Note that due to its movement and computation capabilities, a collaborative robot may perform both physical and cognitive sub-tasks. Conversely, a cloud agent (remote cloud or local cloudlet) can perform only offloaded, location independent cognitive sub-tasks that require computation and processing resources. We note, however, that due to their higher computation processing and storage capabilities, cloud agents are more suitable for cognitive sub-task processing than resource-limited collaborative robots. Thus, the selection of suitable actors for task assignment is key to reduce the incurred computation and communication overhead during the execution of HART-centric tasks. Moreover, the interdependent activities of HART members may lead to an increased complexity and resource consumption. To facilitate cost-effective HART task execution, research in the area of decentralized network coordination, adaptive bandwidth resource management with traditional broadband and offloading traffic co-existence, real-time task assignment, monetary, time, and energy cost-aware task offloading strategies as well as collaborative computing, mobility management, and failure avoidance strategies become mandatory.

To execute real-time HART-centric applications in a cost-effective manner, network operators have been looking for reliable, fast, low-cost, and future-proof communication infrastructures. Towards this end, integrated *fiber-wireless (FiWi) access networks* that combine the high capacity and reliability of optical fiber networks with the ubiquity and mobility of wireless networks represent promising network infrastructures (Maier, 2015). FiWi networks are based on optical fiber (Ethernet passive optical network) and wireless Ethernet (WLAN) technologies, which are then unified with their cellular counterparts, to give rise to the so-called FiWi enhanced Long Term Evolution Advanced (LTE-A) heterogeneous networks (HetNets). FiWi enhanced mobile networks offer several benefits for low-latency HART task execution. First, they exploit the locality of different HART task and cloud agent/robot resources for local/non-local HART task execution. Second, placing a decentralized resource coordinator at the optical-wireless interface of FiWi enhanced mobile networks may play a major role in avoiding higher delays due to task request routing and task allocation to suitable HART members/actors, including their re-allocation in case of failures.

FOCUS OF THE ARTICLE

For beneficial human mobile device and collaborative machine (robot and cloud agent) coactivity-based HART task execution, this chapter first discusses the related work and open challenges in Background section. This section also identifies several key technologies and limitations of existing actors (i.e., robot, cloud agents) selection schemes for MU's device HART task execution. To tackle some of the existing challenges, this work then proposes a latency sensitive HART task migration scheme in the section of proposed HART task coordination that efficiently assigns tasks among human mobile users (MUs), central and decentralized computational agents (cloud/cloudlets), and collaborative robots across converged FiWi network infrastructures. Specifically, to satisfy the task execution requirements, this section of the book chapter investigates when and where (e.g., robot and cloud agent) a MU's computation-intensive task is migrated for execution considering task characteristics, actors (robot and cloud server), bandwidth resources availability, and users mobility. Further, this section describes a bandwidth allocation scheme that allocates timeslot resources to MU's for their broadband and task migration traffic transmission. Furthermore, this section presents an analytical model that analyzes both predicted task execution time and power consumption value of proposed scheme. In evaluation results and findings section, this work

examines the numerical performances of our proposed migration scheme in comparison with traditional baseline schemes. Future research direction section outlines open research issues for HART task coordination over FiWi enhanced Tactile Internet infrastructures. Finally, in the conclusions section, this book chapter summarizes our findings.

BACKGROUND: RELATED WORKS AND RESEARCH CHALLENGES

H2R/M communication based Tactile Internet application execution sets demanding requirements for future access networks in terms of latency, reliability, and capacity. To achieve the Tactile Internet's key requirements of very low latency and ultra-high reliability, recently in (Beyranvand, 2017), the authors proposed the concept of so-called FiWi enhanced LTE-A HetNets that unify coverage-centric 4G mobile networks and capacity-centric FiWi broadband access networks based on data-centric Ethernet technologies. The authors showed that an average end-to-end latency of 1 millisecond and almost guaranteed availability can be achieved in FiWi enhanced LTE-A HetNets by means of fiber backhaul sharing and WiFi offloading capabilities. Note, however, that only conventional human-to-human (H2H) communications was considered in (Beyranvand, 2017), without any coexistent H2R/M or M2M communications. To realize low-latency H2R communications in the Tactile Internet, in (Maier, 2016) the authors discussed the role of several key enabling technologies, including FiWi enhanced LTE-A HetNets, cloudlets, cloud robotics, and mobile-edge computing (MEC), among others. To extend the capabilities of both tele-operated and networked robotics for different Tactile Internet applications, they also elaborated on the importance of a cloud robotic architecture that leverages the combination of an ad-hoc cloud formed by M2M communications among participating robots and an infrastructure cloud enabled by machine-to-cloud (M2C) communications between robots and the remote cloud. Moreover, by leveraging on the improved throughput, reliability, and delay performance of FiWi enhanced LTE-A HetNets, the authors reported that MEC/cloudlet enhanced FiWi multi-robot infrastructures will be essential for the coordination of low-latency Tactile Internet applications.

To offer enhanced quality of service for the execution of HART-centric Tactile Internet applications, in (Chowdhury, 2017a) the authors discussed the potential of suitable human-to-robot task allocation strategies, which emerged as an interesting research problem, taking a wide variety of task (e.g., task location, workload), robot capabilities (CPU speed, moving speed, remaining energy), and failure during task execution into account. The authors indicated that suitable robot selection schemes are mandatory to reduce the task execution latency and energy consumption of MUs and robots. At present, research in the area of H2R task allocation is in its infancy. In (Trigui, 2014), the authors proposed a robotic task allocation scheme that considers only a robot's distance to a given task location for suitable robot selection. A decentralized task allocation framework was proposed in (Mendonça, 2013), where task requests with higher priority are allocated before lower-priority tasks, though task re-allocation and failure avoidance were not studied. In (Choudhury, 2009), the authors presented a role-based robot selection mechanism that depends on the matching of the task type and the robot's skill. Most of the aforementioned studies on suitable robot selection focused mainly on the involved robots' task processing power or distance. To render the HART-centric task allocation more effective, additional robot properties (e.g., availability, skill, mobility, minimum distance to task location, and energy consumption) need to be considered.

Despite ongoing developments in the robotic industry, the selected robot may not always satisfy given task deadline requirements of many computation-intensive tasks due to limited resources (e.g., CPU speed, storage, or battery power). To overcome these problems, robots may utilize the resources

of other collaborative HART members, e.g., cloud servers/agents. Mobile cloud computing (MCC) has emerged as a potential solution for resource limited robots/mobile devices, which allows mobile devices to offload their computation-intensive tasks fully or in part to resource rich surrogates/cloud servers for processing (Deng, 2015). Note that task offloading to remote cloud servers may not always improve a mobile device's task execution latency due to increased wide area network (WAN) delays. To overcome this burden, the concept of MEC has emerged, which allows mobile devices to offload computation intensive tasks to nearby edge cloud servers/cloudlets for processing. To reduce the communication latency of remote cloud servers, cloudlets may be placed at the network edge (e.g., base stations) in close proximity to MUs (Maier, 2016). Different from data offloading, the computation task offloading life cycle involves the following activities: task input data uploading from mobile device to surrogate/cloud server, offloaded task processing (computation workload) by surrogate/cloud server, and task result downloaded by the mobile device from the surrogate. Hence, for better task execution performance, the decision of whether or not to offload the task to a cloud server depends on several important factors such as why offloading is required (e.g., improve task execution time or save energy), who wants to offload the task (e.g., robot, mobile device, laptop computer), offloading environment (e.g., static, dynamic), different task properties (e.g., workload), offloading infrastructure (remote/edge cloud computing), and bandwidth, among others.

Toward this end, taking the idea of task offloading a step further, task migration has emerged as a promising option to improve the quality of experience (QoE) of MUs, whose location changes due to mobility (Gkatzikis, 2013). Task migration broadens the scope of conventional computation task offloading by not only transferring the task from an MU to the cloud server, but also from one cloud server to another one for execution. Task migration is beneficial for low-latency applications only if the anticipated task execution time at the new cloud server is smaller than that of the previous server. Hence, the question of how and where an MU's task should migrate is an interesting research challenge for low-latency HART-centric task execution. To answer this question, several aspects need to be considered, e.g., information about the state of the current host and tentative destination server, the number of tasks running on each server, and the incurred task migration latency.

At present, only a few studies exist on task migration that exploit cloud agents for MUs' migrated task execution. In (Yaqoob, 2017), the authors proposed a task migration mechanism, where suitable cloud agents are selected based on their higher task workload processing speed (CPU speed). In (Zhu, 2014), the authors proposed a real-time task scheduling scheme, in which the cloud server providing minimal energy consumption of the host mobile device is selected for migrated task processing. In (Shi, 2017), the authors proposed a task assignment scheme, in which an MU's task is migrated to a remote cloud server offering a lower predicted task workload processing delay. In (Gkatzikis, 2014), to minimize the transmission delay, the cloud server that is near the MU's task result download location is selected for task migration. Most of the existing studies on task migration considered either infrastructure-based cloud (remote cloud and cloudlet) or infrastructure-less cloud resources (mobile ad-hoc clouds) for task migration. Note, however, that these previous studies did not include different task properties (e.g., task arrival time and number, task workload, migrate task data size, and task deadline), bandwidth, and cloud agent properties (e.g., CPU speed, storage, location) for task assignment to suitable robot/cloud actors. Furthermore, they did not present any bandwidth allocation scheme serving both broadband and task migration traffic at the same time. Importantly, deployment scenarios considering different cloud agents/nearby mobile devices that may fail to satisfy given task offloading requirements have not explicitly studied in the past. There is also a lack of a multi-task resource scheduling mechanisms accounting for both user mobility and cloud agent failure avoidance. Finally, the performance evaluation of HART task

migration schemes in terms of both task execution time and energy consumption is missing as well. More specifically, no existing studies are available to calculate the various HART task completion delay components, including upstream and downstream task request transmission time, task workload processing, communication delay, offload packet buffering delay, and waiting delay at the cloud agents/robots.

PROPOSED HART TASK COORDINATION SCHEME

Network Architecture

Figure 1 depicts our proposed FiWi based Tactile Internet infrastructure used for enabling and coordinating HART-centric task coordination process, whereby humans, collaborative robots, and cloud agents actively participate in the joint task execution process. Our proposed FiWi based Tactile Internet infrastructure consists of a time division multiplexing (TDM) or wavelength division multiplexing (WDM) IEEE 802.3av 10 Gb/s Ethernet Passive Optical Network (10G-EPON) with a fiber backhaul range of 10-100 km between the central optical line terminal (OLT) and remote optical network units (ONUs). The OLT collocated with the central office serves three different subsets of ONUs, which are connected through a 1:N optical splitter/combiner at the remote node. One subset of ONUs may be equipped with a mesh portal point (MPP) and are henceforth referred to as ONU-MPPs, whereby mesh points (MPs) act as intermediate relay nodes between MPPs and mesh access points (MAPs). To provide 4G cellular services to MUs, another subset of ONUs is connected to an LTE enhanced nodeB (eNB) base station, giving rise to so-called ONU-eNBs. The central cloud servers are connected to the OLT via dedicated fiber links. In addition, local cloudlets are connected via dedicated fiber links to ONU-MPPs at the edge of our FiWi based Tactile Internet infrastructure in order to provide cloud services in close proximity

Figure 1. FiWi based Tactile Internet Infrastructures for HART Task Coordination

to nearby MUs and/or robots. For predicting the location of a given MU's task request transmission and task result reception, we adopt the widely used random waypoint (RWP) model (Deng, 2015).

Robot and Cloud Agent Selection for HART Task Execution

Our proposed latency sensitive HART task migration scheme, which selects a suitable robot for physical sub-task (e.g., image capturing at a task location) execution and a suitable agent (central cloud/local cloudlet/nearby robot) for cognitive sub-task (e.g., face detection from captured image) execution includes the following steps. Initially, an MU sends her full task request (both physical and cognitive sub-tasks) to the associated ONU (e.g., ONU-MPP/ONU-eNB). The task request message consists of information about the involved task type, task location, workload, deadline as well as the MU's initial location, speed, and task result download location. Subsequently, the ONU sends the task request to the OLT. Next, the OLT forwards the task request message to the host ONU (task coordinator) that serves at the respective task location. The task coordinator located at the host ONU receives the task request message and forwards it to all involved actor nodes (collaborative robots/robots and cloud agents). The actor nodes in turn send the task response message to the task coordinator node. Each actor's task response message contains information about the actor's task processing capability, busy time, and remaining energy. After receiving all actor nodes' task response messages, the task coordinator computes the predicted full task and physical sub-task execution time of all robots and cognitive sub-task execution time of all agents. In the non-migration scheme, the initially selected robot executes the full task. A suitable robot is selected according to the following criteria: satisfaction of task deadline, sufficient remaining energy, and minimum predicted task execution time among all robots.

Figure 2. Proposed Bandwidth Resource Management Scheme

Unified Bandwidth Assignment

As shown in Figure 2, in our proposed resource management scheme, the central OLT assigns bandwidth resources to ONUs (ONU-MPP/ONU-eNB) in the optical fiber backhaul via exchange of IEEE 802.3ah multipoint control protocol (MPCP) messages (REPORT and GATE). The ONU uses the REPORT message to inform the OLT about its next upstream transmission opportunity. The GATE message is used by the OLT to inform the ONU about its next upstream transmission timeslot. In the wireless front-end, ONUs assign bandwidth resources to associated wireless stations (STAs), which may be MUs or robots, via exchange of IEEE 802.11 messages, e.g., Beacon/PS-Poll message exchange between ONU-MPP and STAs for WLAN services and random-access preamble (RAP)/random access response (RAR) message exchange between ONU-eNB/STAs for cellular services (Hasan, 2013).

STAs use the PS-Poll/RAP message to inform ONUs(ONU-MPP/ONU-eNB) about their required bandwidth demands for the next polling cycle. Conversely, an ONU - upon reception of their own GATE message reception from the OLT - selects a suitable robot/cloud agent for each arriving task request, divides its timeslots into broadband and task migration sub-slots, and then assigns each time sub-slot to its associated STAs(MU/robot). Subsequently, the ONU sends a Beacon/RAR message to the STAs, which includes its assigned time sub-slot map for the next polling cycle. ONUs select suitable actors for each task request via exchange of DHCP messages (Discover-Offer-Request-Ack) between ONUs and involved actors(cloud/cloudlet/robot) (Rawadi, 2014). During their task migration upload sub-slot, STAs migrate their cognitive sub-task input data to the selected cloud agent for execution. In contrast, during their task migration download sub-slot, STAs receive the processed task result from the selected agent. For further technical details, the interested reader is referred to (Chowdhury, 2018).

Predicted Task Execution Time Calculation

In this work, full task execution time includes the time duration between task assignment by task coordinator to suitable actors and task result reception by human mobile users. Hence, the predicted full task execution time of the non-migration scheme (only robot based) is calculated as follows:

$$t_{nm} = t_j^p + t_j^c = t_j^w + \frac{d_j^i}{q_m} + \frac{x_p}{q_p} + \frac{x_c}{q_p} + t_{j \rightarrow u}^r,$$

where t_j^p , t_j^c , t_j^w , d_j^i , q_m , q_p , x_p , x_c , and $t_{j \rightarrow u}^r$ denote the physical sub-task execution time of the robot, cognitive sub-task execution time of the robot, busy time of the robot, distance between the robot and the task location, the robot's moving speed, task workload processing speed, physical sub-task workload, cognitive sub-task workload, and task result transfer time (robot to MU), respectively.

Figure 3. Task Execution Time Evaluation

Power Consumption Value Calculation

In this work, STA's power consumption for full task execution includes the estimated power consumption of STA's (MU's and robots) for both physical and cognitive sub-task workload processing.

A wireless station's power consumption for full task execution in the non-task migration scheme is given by:

$$e_{nm} = e_j^p + e_j^c = p_i * t_j^w + p_m * \frac{d_j^i}{q_m} + p_s * \frac{x_p}{q_p} + p_c * \frac{x_c}{q_p} + p_d * t_{j \rightarrow u}^r,$$

where p_i , p_m , p_s , p_c , and p_d denotes the wireless station's average power consumption (per time unit) during the robot's busy time, moving time to task location, physical and cognitive sub-task workload processing time of the robot, and task result reception time, respectively. Hence, in our proposed full task execution with cognitive sub-migration scheme, both robot and agent are selected for executing the physical and cognitive sub-task, respectively. If more than one robot and agent satisfies both remaining energy and deadline criteria of the physical and cognitive sub-task, a suitable robot and cloud agent is selected based on the minimum predicted physical and cognitive sub-task execution time, respectively. Similarly, the full task execution time for task execution with migration (robot physical and agent cognitive sub-task execution) scheme is given by:

$$t_{wm} = t_j^p + t_a^c = t_j^w + \frac{d_j^i}{q_m} + \frac{x_p}{q_p} + t_{j \rightarrow a}^u + t_a^w + \frac{x_c}{q_a} + t_{a \rightarrow u}^d,$$

Figure 4. Power Consumption Evaluation

where t_j^p , t_a^c , t_j^w , t_a^w , q_a , $t_{j \rightarrow a}^u$, and $t_{a \rightarrow u}^d$ represent the physical sub-task execution time of the robot, cognitive sub-task execution time of the agent, busy time of robot and agent, agent cognitive sub-task workload processing speed (a=central cloud/cloudlet), cognitive sub-task upload (robot to agent), and task result download time (agent to MU), respectively. A wireless station's power consumption for the task execution with migration scheme is given by

$$e_{wm} = e_j^p + e_a^c = p_i * (t_j^w + t_a^w) + p_m * \frac{d_j^i}{q_m} + p_s * \frac{x_p}{q_p} + p_u * t_{j \rightarrow a}^u + p_a * \frac{x_c}{q_a} + p_d * t_{a \rightarrow u}^d,$$

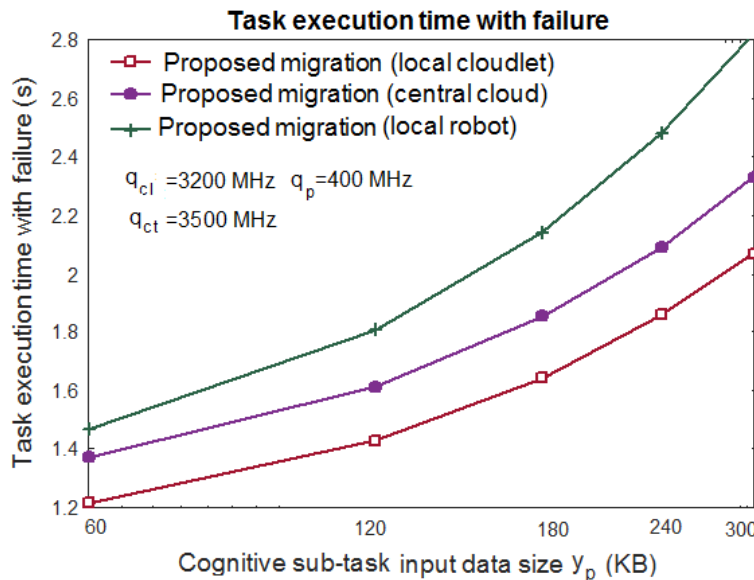

where p_r , p_m , p_s , p_a , p_u , and p_d denote the wireless station's average power consumption (per time unit) during the robot's busy time, moving time to task location, the robot's physical sub-task workload processing time, the agent's cognitive sub-task workload processing time, cognitive sub-task upload and task result reception time, respectively.

EVALUATIONS RESULTS AND FINDINGS

In the following, we investigate the performance of our proposed task migration scheme. For selecting a suitable task execution scheme, we compare the performance of the following four different schemes: (i) baseline scheme with no migration, (ii) proposed cognitive sub-task migration scheme (latency sensitive), (iii) baseline migration (maximum processing speed), and (iv) baseline migration (minimum distance).

In the no-migration scheme, only the initially selected robot (with minimum predicted execution delay among all robots) executes the full HART task that consists of both physical subtask (image capturing at task location) and cognitive subtask (face detection from captured image). Conversely, in the proposed migration scheme (latency sensitive), the initially selected robot executes the physical subtask

Figure 5. Task Execution Time with Failure Evaluation+--*

and migrates the cognitive subtask to a suitable cloud agent for execution. Hence, both the robot and cloud agent are selected based on their respective predicted lower physical and cognitive task execution time value, respectively. By contrast, in the baseline migration (maximum processing speed) scheme and baseline migration (minimum distance) scheme, actors (robot and cloud agent) are selected based on their maximum task processing speed and minimum distance, respectively. In case of multi-task arrivals, we assume that both actors (cloud agent/robot) and bandwidth resources are assigned to each task in a first-come-first-served (FCFS) manner. We also assume that each actor node is able to process only one sub-task (either physical or cognitive) at any given time. For evaluation, we vary the physical sub-task workload (x_p) and cognitive task workload (x_c), cognitive sub-task input (y_p), and output data size (y_c), and task deadline (t_d) values in compliance with (Zhang, 2013) and (Zhang, 2015). The legend in Figure 3 shows the default parameter settings of x_p , x_c , y_p , y_c , and t_d used in our evaluation.

Figures 3 and 4 highlight the task execution time and power consumption of the different schemes under consideration, respectively. Both figures show that the task execution time and power consumption grow rapidly for increasing cognitive sub-task input data size in all compared schemes. Both figures indicate that the minimum task execution time and power consumption are achieved in our proposed task migration scheme (latency sensitive). Among all compared schemes, the baseline migration (minimum distance) scheme exhibits the worst task execution latency performance, though it helps improve the power saving of the baseline scheme (non-migration scheme) due to the cognitive sub-task migration to another nearby actor at minimum distance.

Figure 6. Task Completion Delay Evaluation

We observe that both baseline migration (maximum processing speed) and baseline migration (minimum distance) don't outperform our proposed migration scheme (latency sensitive) in terms of task execution delay and power consumption. This is because in both schemes, either the maximum processing speed of the actor or the minimum distance is considered for selecting a suitable actor, respectively, but not both at the same time. Conversely, in our proposed scheme, suitable actors (robot/cloud agent) are selected based on the minimum predicted task execution time, including the robot/agent's physical/

cognitive sub-task workload processing delay, communication delay, and waiting delay at the robot/agent. For instance, for a typical cognitive sub-task input data size of 180 KB in Figure 3, our proposed migration scheme yields a 7.05%, 25.7%, and 18.55% higher task execution time efficiency than the baseline migration (maximum processing speed), baseline migration (minimum distance), and baseline scheme (no migration), respectively. For the same offload packet size of 180 KB in Figure 4, the achieved power consumption efficiency in our proposed scheme with regard to the baseline migration (maximum processing speed), baseline migration (minimum distance), and baseline schemes (no migration) is 7%, 4%, and 27% higher, respectively.

Figure 5 investigates the suitability of different actors for cognitive sub-task execution in case of initially selected cloud agent failure. The figure shows that compared with the central cloud (remote) agent and nearby local robot task migration schemes, the local cloudlet agent migration scheme experiences a lower task execution time delay due to its lower cognitive sub-task migration communication overhead and workload processing delay. Finally, Figure 6 illustrates the impact of the polling cycle time on the end-to-end task completion delay. Note that the end-to-end task completion delay is obtained by taking the time between task request transmission and task result reception by the MU. We observe that the task completion delay is small for lower polling cycle times and grows rapidly for increasing polling cycle time in all compared schemes. The figure also shows that for both longer and shorter polling cycle times, our proposed task migration scheme (latency sensitive) achieves a significantly lower end-to-end task completion delay than its counterparts and is thus more suitable. For instance, for a cognitive sub-task workload of 240 Mcycles, polling cycle time of 350 ms, total number of 16 ONUs, and FiWi traffic load of 0.6, the task completion delay efficiency of our proposed task migration (latency sensitive) scheme compared to the baseline (non-migration) and baseline migration (minimum distance) migration scheme is 13% and 18% higher, respectively.

FUTURE RESEARCH DIRECTIONS

Interesting future research studies that build on our proposed task migration scheme may unfold in the following possible directions. HART members can share their bandwidth, computation, and storage resources to stimulate beneficial cooperation, which in turn help cut down users' energy consumption and data usage cost. Hence, an efficient auction-based resource provisioning policy is mandatory to find the optimal price for human mobile users requesting task execution services. Another future research area of interest involves the use of HART task coordination for mixed-reality applications. For a cost-effective roll-out of mixed-reality applications, the development of adaptive real-time synchronization and computation techniques is another interesting direction of future research.

CONCLUSION

We investigated the challenges and benefits of HART-centric task execution over FiWi enhanced Tactile Internet infrastructures. To achieve higher task execution time and power consumption efficiency, we proposed a latency sensitive task migration scheme that selects a suitable collaborative robot for physical sub-task and a cloud agent for cognitive sub-task execution by taking a wide variety of task characteristics and actor (robot/cloud agent) resources into account. Further, we presented a resource allocation scheme that assigns bandwidth for transmission of broadband and task migration traffic over

FiWi network infrastructures. We presented comparison results of both HART task execution schemes with migration and without migration. Our presented results show that for a typical 120 KB (migrated) cognitive sub-task input data size, the achieved task execution time and power consumption efficiency in our proposed task migration scheme with regard to the baseline task execution (no migration) are improved by approximately 14% and 22.77%, respectively. Moreover, our obtained results highlight that when the initially selected agent node suffers from failure, local cloudlet agent cognitive task migration is more beneficial than remote cloud agent or local robot migration in terms of lower task execution time. Thus, our proposed task migration scheme is more suitable for lowering delay and power consumption inhuman-machine coactivity based on low-latency HART task execution.

KEY TERMS AND DEFINITIONS

Fiber-Wireless Enhanced Networks: Traditional FiWi access networks are based on integration of both optical fiber (Ethernet passive optical network or EPON) technologies (at the wired backhaul) and wireless (wireless local area network or WLAN) Ethernet technologies (at the wireless frond-end), which are then integrated with their cellular counterparts, namely, 4G Long Term Evolution Advanced (LTE-A), to give rise to FiWi enhanced LTE-A heterogeneous networks (HetNets).

Human-Agent-Robot Teamwork (HART): Human-agent-robot teamwork (HART) denotes the task and resource coordination framework for executing a requested task in a collaborative setting, in which human mobile device transfers the task request and receives the task result from collaborative machines (robot/cloud agent) after processing. Whereas, the robot and cloud agent process the physical (movement towards task location and image capturing using camera) and cognitive sub-task (face detection from captured image), respectively. Note that, in this work the robot uploads the physical sub-task output data size (input of cognitive sub-task) to cloud agent for processing. Hence, the cloud server/agent transfers the processed cognitive sub-task results to human MU's device after processing.

Mobile-Edge Computing: Mobile-edge computing (MEC) technology offers decentralized cloud computing services (e.g., computing storages) to mobile users' devices for executing their computation-intensive tasks/applications by setting up local cloud servers/cloudlet/fog servers at the network edge (WiFi/cellular base station) in close proximity to mobile users through a process named as computation offloading.

Predicted Task Execution Time: Predicted task execution time denotes the time interval between task request assignment by task coordinator to suitable actors (robot/cloud server) and task result reception by human MU's device.

Tactile Internet: The tactile internet is defined as a very low-latency communication system that ensures very low round-trip delay along with high availability, reliability, and security for real-time human-machine interaction-centric applications execution.

Task Migration: Contemporary mobile devices offload large amounts of computationally intensive tasks to resource-rich cloud servers for processing. Task migration broadens the scope of conventional computation task offloading by not only transferring the task from an MU to cloud servers/surrogates but also from one cloud server/surrogate to another one for execution.

Embedded Control System Design for Inverted Pendulum Type Mobile Robots Based on High-Level Petri Nets

Gen'ichi Yasuda

Nagasaki Institute of Applied Science, Japan

INTRODUCTION

In recent years, functionality and complexity of real-time controllers dramatically increased, beyond the complexity of hardware components. Due to the growing complexity of the software components in advanced multiprocessor-based robot controllers, including timing requirements of run-time elaboration of information from multiple external sensors, the need of early validation of the design of control software is increasing (David & Alla, 1994; Hruz & Zhou, 2007). Usually, control laws for non-linear physical systems like robotic vehicles and arms are specified in continuous time and allows for checking mainly qualitative properties like stability. At run time, these control laws are integrated and implemented as multi-tasks programs controlled by a real-time operating system on a single or multiprocessor target. The performance indices depend on the actual implementation, including sampling rates and computing latencies, besides the algorithm in use. Conventional research on real-time operating systems for complex robotic system control do not provide tools to analyze or synthesize such sampled control laws with respect to performance indices, measuring the impact of the organization of the control system on the overall controlled process. For the design and implementation of the overall software of real-time robotic control systems, while traditional techniques, such as finite state automaton, offer limited support for validating control algorithm design, the use of formal methods can increase the possibility of validating design.

This chapter presents a formal approach to designing software for sensor based non-linear motion control with a backstepping method (Khalil, 2002), focusing on the design of control software for non-holonomic two-wheeled inverted pendulum mobile robots (Nomura, 2009). Because the hardware of the control system exhibits subsystems with different dynamics, for example, feedforward paths to update some parameters and measurements to come from sensors of different kind running at different rates, control algorithms are decomposed into groups of cooperating tasks; where these tasks with different executing durations run in sequence or in parallel. Multi-task programs with multi-rate controllers permit modular programming and software reusability. The feature can be useful to optimize computing resources, because both onboard space and energy are strongly limited, especially for autonomous robots working in unstructured or critical environments.

BACKGROUND

To perform complex control software using multiple sensors and effectors, single or multiple computer control systems are essentially employed, where the overall management of a computer system is under

DOI: 10.4018/978-1-7998-3479-3.ch004

control of a multitasking operating system master program, which is referred to as a supervisor, monitor, or kernel. The master program is a collection of programs to schedule the jobs, to manage the hardware resources, and to provide a more hospitable interface to the user programs. So centralized operating systems have become so essential to efficient computer operation, viewed as inseparable from the hardware.

The simple Petri nets associate events with transitions and conditions with places. Places and transitions are linked by directed edges called arcs. Since the presence of a token in a place indicates that the corresponding condition is true, the marking describes the state of the Petri net in terms of conditions which are true and those which are false. When each of the input places becomes marked, i.e. has a token, the transition fires, i.e. the event occurs, and the firing removes a token from each of the input places, making the preconditions false, and deposits a token in each of the output places, making the postconditions true.

The Petri net is gaining increasing importance for the discrete event modeling and analysis of robotic control systems, since it offers a convenient way of expressing system behavior which is both parallel and asynchronous, and therefore distributed (Wang & Sarides, 1993; Yasuda, 2014; 2015a). In addition to the precedence constraints among computing modules, including sequences of modules and the repetition of certain modules, looser couplings associated with shared resources, such as memory and devices, can also be directly expressed. Besides modeling capabilities, the Petri net can be analyzed in a formal way to obtain information about the dynamic behavior of the modeled system (Du et al., 2013).

DISTRIBUTED CONTROLLER DESIGN BASED ON BACKSTEPPING APPROACH

A wheeled inverted pendulum mobile robot is a self-balancing, traveling vehicle with two wheels attached on the sides of its body. Two motors are attached between the wheels and the body to control traveling speed and direction, besides its own posture. Both the traveling motion and the self-balancing are achieved by independent actuators providing the necessary torques to the wheels (Fierro & Lewis, 1997; Nomura, 2009; Takei et al., 2009). The complete dynamics of the traveling motion consists of the steering kinematics and the vehicle dynamics. The nonholonomic constraint states that the vehicle can only move in the direction normal to the axis of the driving wheels, satisfying the conditions of pure rolling and non-slipping. For traveling control, divided into tracking a reference trajectory, following a path, and point stabilization, the software generates robot trajectories based on on-line elaboration of sensors information and manages kinematic inversion. According to a backstepping approach, the main idea behind nonlinear feedback control for solving these problems is to define velocity control inputs based on the perfect velocity tracking assumption. According to a backstepping approach, nonlinear feedback control for solving these problems velocity control inputs are defined based on the perfect velocity tracking assumption. So, velocity control inputs should be converted into torques, taking into account the actual vehicle dynamics.

For balancing control, the posture angle x_1 and its derivative $x_2 = \dot{x}_1$ are used as the state variables, where the posture angle is 0 when the center of gravity of the robot is right above the contact point of a wheel to the ground. The reference values of the posture angle and the angular velocity are zero. The state-space equations of balancing control are generally represented as follows:

$$\begin{aligned}\dot{x}_1 &= x_2 \\ \dot{x}_2 &= \frac{1}{g_1(x_1)}(u - h(x_1, x_2))\end{aligned}\quad (1)$$

As a first step of backstepping approach, the virtual control law is defined such that for the posture angle error $z_1 = x_1^{ref} - x_1$, $\lim_{t \rightarrow \infty} z_1(t) = 0$, as follows:

$$\alpha = k_1 z_1 + k_2 \int z_1(\tau) d\tau \quad (2)$$

where k_1 and k_2 are positive constants.

Then, an input torque u is designed such that for the error $z_2 = \alpha - x_2$, $\lim_{t \rightarrow \infty} z_2(t) = 0$. The first and second Lyapunov functions are defined as:

$$V_1 = \frac{1}{2} z_1^2 + \frac{k_2}{2} \left(\int z_1(\tau) d\tau \right)^2 \quad (3)$$

$$V_2 = V_1 + \frac{1}{2} z_2^2 \quad (4)$$

Differentiating V_2 as follows:

$$\dot{V}_2 = \dot{V}_1 + z_2 \dot{z}_2 = -k_1 z_1^2 + z_1 z_2 + z_2 \dot{z}_2 \quad (5)$$

For $\dot{V}_2 < 0$, $\dot{z}_2$ is chosen as follows:

$$\dot{z}_2 = -k_3 z_2 - z_1 \quad (6)$$

where k_3 is a positive constant.

Consequently, the input torque is determined as:

$$u = G(z_1, \int z_1(\tau) d\tau, z_2) \quad (7)$$

Since $\dot{V}_2 \leq 0$ is derived, it is ensured that the tracking error converges on zero.

Figure 1 shows the overall structure of software modules for generating motion control of two-wheeled inverted pendulum mobile robot. The motion controller mainly consists of the following cooperative computing modules: path planning, self-localization, motion planning, motion monitoring, balancing and traveling control, and exteroceptive sensing (wheel rotation and angular velocity sensing, and body posture angle and angular velocity sensing). The software module for balancing and traveling control obtains the wheel rotational angles and their angular velocities and the body posture angle and angular velocity from the respective sensing modules at each sampling time and controls the torque of the two

motors. The gyro sensor output voltage is proportional to the body posture angular velocity and the posture angle is obtained by an accumulation of the angular velocity, where scale factors of offset or drift and sensitivity of the sensor are calibrated. The self-localization module estimates the robot position based on odometry through the traveling distance and orientation of the body obtained from the wheel rotation and angular velocity module, which are calculated by counting the number of encoder pulses.

The path planning module computes nominal trajectories in terms of positional setpoints or subgoals in the operational space and passes to the motion planning module, which corrects them according to balancing control, performing velocity calculation by kinematic inversion, both with a repetition interval of 10 ms. The motion planning module generates a plan of motion, including velocity pattern and moving direction, to the next subgoal. The traveling control module communicates with the motion planning module and executes micro-interpolation and position control in joint space of the vehicle at a sampling interval of 1 ms. The robot travels from a subgoal to the next subgoal along a given path on the map while keeping its posture. At each subgoal, the completion signal is sent to the monitoring module, and the estimated position is adjusted using laser range sensor data and the map. Figure 2 shows a view of the wheeled inverted pendulum mobile robot using LEGO Mindstorms NXT.

Figure 1. Software structure of motion control of two-wheeled inverted pendulum mobile robot

Figure 2. View of experimental mobile robot

Additionally, some sensor modules are provided to handle the acquisition of exteroceptive gyro sensor data and encoder pulses from the wheels. The overall control system has been configured to introduce exteroceptive sensor-based control capabilities as an evolution of the current industrial controller. The control unit is based on the VME-bus and includes a multiprocessor board equipped with Motorola 68020/68882 CPU's for path and motion planning, and a DSP (Texas 320C25) for balancing control and traveling control. During control of physical processes, data always flow from sensors to actuators along several control paths. Since feedforward paths and parameter adjustments are typically executed more slowly (less frequently) than feedback error computations, multi-rate sampling can optimize computing power.

DISCRETE EVENT MODELING AND CONTROL NET REPRESENTATION

The control system development methodology consists of three phases to assist Petri net based implementation of the control software. In the first phase, the robotic task and environment requirements are specified to identify functionalities and attributes of the hardware and software architecture needed to complete the task. In the second phase, the net model for system control is designed as follows. First, the net model of the task or recipe specifications is constructed using the task-oriented approach. Second, the net model of resource specifications corresponding to each task specification is provided using the mutual exclusion concept. Then, the task and resource net models are integrated to yield the basic net model for system control. In the third phase, by analyzing and refining the basic net model, a deadlock-free, safe, and reversible system net model is obtained. For non-centralized distributed control, the system net model may be decomposed with respect to resources, into net models of communicating intelligent subsystems, which are autonomously operated using corresponding resources or devices.

A customized Unified Modeling Language (UML) framework (Eshuis & Wieringa, 2004) is used to describe every component of the control system, including class attributes, methods, and their relations of inheritance, composition and association providing a structural view of the software with the hardware locations of the components. Based on the above class diagrams, the interaction sequence and the messages passed among classes are described using UML sequence, collaboration, and use-case diagrams. The statecharts are generated to provide a global view of the inherent states of the software components behavior. Then, the dynamics of the UML schematics is translated to Petri nets. Nowadays, the state diagrams or statecharts are adopted to extract the discrete event system dynamics of the UML framework design. Statecharts are designed as state machines and built by initial and final pseudostates, and transitions having one input state and one output state. Each transition arrow has a label with three optional parts: event, condition, activity; if the current state is the specified source state and the appropriate event occurs with the specified condition, the transition is fired and the specified action is taken. The translation from a UML statechart to a Petri net is simple such that each statechart start is converted into a Petri net place and each statechart transition into a Petri net transition with corresponding labels and tokens. Finite state machines are equivalently represented by a Petri net subclass, where a place having two or more output transitions is referred to as a conflict, decision or choice and the representation of the synchronization of parallel activities does not be allowed.

The execution of an active program with finite duration can be modeled with two events; start transition that represents the beginning of the computing action, end transition that represent the termination of the action, and place that models the action in progress. Figure 3 shows a Petri net model of computing module in motion control software. Based on a bottom-up approach, the first terms to be designed are

the device-level tasks or closed loop control laws encapsulated in a reactive logical behavior. The main features of the device-level control software are modeled using extended notations based on the ordinary Petri nets, where events are modeled by transitions as instantaneous actions occurring in a system. States can either represent a passive condition, such as waiting for input data, or the execution of an active program, for path planning, object recognition, or control computation. In repetitive execution, control data can be associated as integer iteration number with tokens in order to control transition firing by means of predicates. As a simple representation of interaction with the environment, a firing transition may trap sensory data and send output data to actuators. The transitions behave as agents for communication with the environment by use of the pre- and postprocessors of a firing transition; an enabled transition can call a preprocessor before it starts firing and after firing it can call a postprocessor. The preprocessor also sends signal to the actuator to turn on its effector.

Figure 3. Petri net model of computing module in motion control software

A task is the maximum granularity considered by the control systems engineer at the device control level, characterizing continuous time closed loop control laws, with their temporal features related to the management of associated events. The continuous time specification is translated into a description by adding temporal properties, such as discretization of time, durations of computations, communication and synchronization between the involved processes. Consequently, each task is defined in terms of communicating real-time computing modules, which each implement an elementary part of the control law. Most of the modules are periodically executed, generating interrupts needed to activate control tasks each sampling time with a real-time clock, to perform the calculations involved in the computation of the control algorithm, for example, state observer, estimation, sensor output compensation, kinematic inversion, calculation of virtual control, and calculation of control torque. Furthermore, other modules monitor conditions, which are classified into preconditions, post conditions, and exceptions like reaching a task space limit, and may trigger events participating in the reactive management of the task. A typical task is sequentially composed of the following modules: reading an input port, performing a calculation, and writing to an output port, and may be modeled by a condition/event net with three transitions for start and end of the actions and a transition generating interrupts with different periodic events by a real-time clock which is also modeled by a Petri net. By associating durations with transitions or places, a timed Petri net can be obtained. Considering the duration of calculation of the transitions, reading and writing can be assumed to be instantaneous events.

DESIGN OF CONTROL AND COMMUNICATION NETS

In case that each module is running freely or independently and the communication does not add synchronization, it can lead to an unexpected ordering of modules at run time by the operating system without any supervisor, which is similar to the unordered instinctive situations at the unconscious level within the human brain. So, to translate control laws into a system net model of task, a synchronization between modules scheme should be adopted for ensuring that the system net model is deadlock free and minimizing computing latencies to improve control performance.

In modeling control software with periodic control and communication laws, a basic property to be ensured is structural deadlock freedom, which means that given any natural initial marking, deadlock cannot occur. This property has corresponding definitions in the Petri net. A Petri net is live with respect to an initial marking if, from any marking in the set of markings reachable from the initial marking, there exists for each transition a legal firing sequence leading to a marking in which that transition is enabled. Because deadlock arises when no transition can be longer enabled, liveness implies deadlock freedom. Partially synchronizing some computing modules can improve the practical performance of the implementation. However, using synchronizations may lead to deadlocks or temporal inconsistencies. The consequences of introducing such synchronization should be examined in terms of structural and temporal problems using Petri net modeling and analysis. Some guidelines about how to add such synchronization are given to design deadlock-free and efficient implementations of real-time periodic control laws (Liu et al., 2013). In case each place has just one input transition and one output transition, that is, each associated condition may only become true in one way and can have one consequence, the task behavior is deterministic and the resulting Petri net is called a marked graph. For a marked graph the token count in a directed circuit is invariant under any firing (Simon et al., 1998). Using the marked graph, parallel construct of modules and their synchronization can be modeled with two transitions (events): transition that enables two parallel modules and transition that fires when both modules are completed, where both start transitions fire with no delay and end transitions are delayed by the duration of the modeled actions of the modules.

Generally, shared memories are used to exchanging data among modules, holding data produced by some modules and consumed by other modules. A shared memory is modeled with a place marked with a token that stores the shared data. Shared memories with capacity 1 and no access control, which store only one value that can be written or read without limitations, can be used for storing sampled data to be used for some modules, because only the most recent value is important regardless of the use of older values (Silva et al., 2014). Figure 4 shows a net model of shared memory.

Figure 4. Petri net model of shared memory

For typical motion commands, the planning module and the sensing module is activated synchronously at the established sampling frequencies as follows. The planning module computes nominal trajectories in terms of operational space position setpoints and passes them to the sensing module, which corrects

them according to measured data and control algorithms and then returns the corrected setpoints to the planning module. Setpoints and corrected setpoints are asynchronously communicated from the planning module to the sensing module and in reverse, respectively, through the shared memory. Trajectory correction is computed and applied to the reference trajectory generated by the planning module. Path profiles are handed over to the planning module. On the other hand, for sensor-based motion commands, the sensor module detects runtime the next goal through a vision or distance sensors and passes a sequence of motion commands or subgoals to the planning module. The communication between the two modules should be asynchronous because the planning module has to complete the execution of the current motion command before it can handle the next one.

The procedure to merge two Petri nets to generate a composed module or task using shared memory is as follows. For corresponding transitions between two Petri nets, a communication place labeled as “Signal sent” or “Buffer” is built, and an output arc from the transition labeled as “Send (Write)” to the place and an input arc from the place to the transition labeled as “Receive (Read)” are added. If there is a transition that corresponds to a transition already connected to a communication place, then an input or output arc between the transition and the communication place is added. Because initial marking of the composed Petri net must be referenced to the Petri nets, numerical labels of places and transitions are reorganized to create a joined marking and transition enumeration for the composed Petri net.

Besides shared memory, different existing components, such as flags, toggles, which satisfy the modeling requirement of the multitasking control applications, can be modeled to link pairs of modules via their ports. As a more practical method of communication between the sender and receiver modules, a flag records a Boolean value with two places, either of which holds a token indicating the current state of the flag, and it can be set to either of its values independently from its previous value. The modules communicate synchronously through a set of shared flags to notify the states of execution of control tasks. For example, when the path planning module is completed, the corresponding flag is set. Then the transitions for the sensing module can be enabled and the module will start. The value of a flag can be tested checking for the presence of a token in the places. Since transitions need to remove a token to test a flag state, they are also required to put the token back so that the state of the flag will be preserved.

Communication between planning and control modules can be asynchronous or synchronous depending motion commands, and the protocol should be modified so that the last or the next available one is the best data for closed-loop control without loss of data. In synchronous communication, each module acts synchronously with the other; the first module to reach the rendez-vous is blocked until the second one is ready. In asynchronous communication, while the sender is running freely and posts messages on its output ports at each period, the receiver either receives the message if a new one is available or is blocked until the next message is posted. Symmetrically, the receiver runs freely, the sender is blocked up to the next request except if a new message was posted since the last receiving.

Although designing a system model of a task using Petri nets promote a modular approach (Fleury et al., 1994; Music & Matko, 1999), mapping each net model to a thread at run time increases operating system overhead due to numerous context switches and inter-process communication under the centralized supervising computer control. Therefore, assigning a group of modules which are sequentially executed to a thread by adding a certain amount of synchronization is desirable, where communication between groups or threads does not add synchronization constraints, so that the synchronization skeleton of the task is not changed. The device-level tasks are logically and temporally composed to build more complex tasks, then the higher-level software is designed in terms of a set of robotic tasks to be executed under a real-time operating system. Figure 5 shows a detailed net model of backstepping controller using shared memory and flags.

Figure 5. Petri net model of backstepping controller

IMPLEMENTATION ISSUES ON A MULTITASK PROCESSING ARCHITECTURE

For periodic and multi-rate modules distributed over a multiprocessor target architecture, various message passing mechanisms over type ports have been implemented. The structure of the periodic modules is provided by separating calculations, communications and calls to the underlying operating system. The temporal attributes of a module for calculation are duration of execution, activation period, input and output ports and their communication protocols, priority for scheduling at run time, and assigned processor in case of a multiprocessors target. The non-periodic reactive behavior of the task is handled by a special module which may be awakened by events coming from the task itself or others; these events represent the external view of the task and are used to compose tasks into more complex tasks.

As a special task for navigation, the console is modeled with the transition, and its input and output places. The transition represents an instruction loader, by popping a command from a queue of commands according to its time-stamp in the input place and putting it in the output place which is connected to the sensor module for execution of sensor-based control algorithms. The abstract data type of the queue is defined with the usual operations such as popping which extracts the top element from the queue, testing which is true if the queue is empty, etc. The place which represents the interface of the sensor contains the current value of the sensor. The input transition simulates the sensor, by updating the value of the token in the place, popped from the queue in the input place of the transition.

Application programs for Petri net based modeling and simulation of discrete event dynamic systems have been developed and used as a real-time control simulator. The Petri net simulator is realized as a toolbox for the MATLAB platform, so that the general purpose MATLAB tools for simulation of communication actions such as SimEvents and SIMULINK can be used in the Petri net models. The MATLAB environment with RWTH-Mindstorms NXT Toolbox allows control of LEGO Mindstorms NXT through Bluetooth wireless connection Data Acquisition Toolbox for receiving and sending input and output signals from/to external sensors and effectors, communicating with USB hardware. The execution of the simulator keeps periodically scanning; in each scan a Petri net is executed in the similar manner as a multitasking real-time operating system. The simulator checks for any enabled transitions. If there is any enabled transition it is placed into a queue-like data structure, then the respective transition definition file is run to make sure whether it can actually fire, satisfying all the guard conditions defined in the file including reserving resources for use by it. If an enabled transition can fire, then it is moved to another data structure. At the same time, input tokens for this transition are consumed from the respective input places. The simulator also checks whether any firing transition is completing. If there is any transition that is completing, then it is removing from the structure and the output tokens

are deposited into the output places of the transition. For optimal management of system resources, the following functions are provided: requesting and releasing resources, declaring and changing priorities of different transitions, and reporting resource usage idle time.

CONCLUSION

Because the backstepping control design can promote distributed implementation of the complex robotic control software, this chapter has described a unified and formal approach of modular, cooperative control software synthesis for complex mobile robot hardware using extended high-level Petri nets. The control software can be executed by simulating the overall Petri net models, such that the simulated behavior is the same as the actual behavior of the controlled objects or sensors and effectors. Consequently, the modeling and control of robotic motion can be executed in real time on a general computing architecture such as a client server system connected on an Ethernet network, where the system controller is the server and the local controllers are the clients. In contrast to conventional multitasking operating systems, the described Petri net based coordination method proposes a non-centralized control scheme without supervisor, monitor, or kernel. For robust-adaptive controller based on neural networks and more complex command tasks with real-time trajectory tracking including obstacle avoidance, the net models can be easily implemented, but it should be more efficiently executed on a high-performance multiprocessor architecture.

FUTURE RESEARCH DIRECTIONS

Due to the use of hierarchical, modular Petri nets, the composition/decomposition strategies for obtaining subnets or agents may be adapted to configure a bio-inspired autonomous intelligent hierarchical agent-based control system, according to the number of processors, the similarity structure of the subnets or the geographical distribution of the subsystems (Yasuda, 2015b; 2016). Each controller can be passively and asynchronously activated as a high-level agent in response to corresponding external and/or internal conditions and independently and concurrently executed. hierarchical agent-based control system. In a hierarchical agent-based control system, some local events, such as program start, end, and failure, generated by lower-level agents are monitored as global events and consumed by the higher-level agents, which globally induce lower-level agents to activate corresponding collective behaviors, like neural correlates of consciousness in human brains.

KEY TERMS AND DEFINITIONS

Backstepping: A technique for designing stabilizing controls for a special class of nonlinear dynamical systems, which are built from subsystems that radiate out from an irreducible subsystem that can be stabilized using some other method. The design process is a recursive structure, starting at the known-stable system and backing out new controllers that progressively stabilize each outer subsystem. In each step a Lyapunov function and a virtual control law are derived for each subsystem.

Deadlock: A situation that occurs when tasks prevent each other from running because of a cyclic locking and requesting of resources. The task may have to wait to acquire any shared resource.

Multitasking: Computer's capability to perform more than one task at the same time, switching from task to task quickly and seamlessly, although it is processing only one instruction at a time.

Shared Memory: A region of memory shared by multiple processes, provided for interprocess communication; each process that accesses shared memory sees the memory as though it were part of that process's private memory space.

Synchronization: In a multitasking system, where tasks interact directly with each other or indirectly through shared resources, coordination of their interaction to prevent undesirable race conditions.

Task: A task is a generic term that refers to an activity carried out by software that occurs independently from other activities in the system. Tasks that are separate executing programs are called processes.

Trajectory Tracking: Given a reference trajectory in the plane, a navigation technique that computes the torque input such that the trajectory error tends to zero.

Wheeled Inverted Pendulum Mobile Robot: A vehicle that controls its own posture, traveling speed, and direction with two wheels attached on the sides of its body.

Semantic and Formal Representation of Cognitive Models for the Metacognitive Architecture CARINA

INTRODUCTION

A cognitive model is a computational model of internal information processing mechanisms of the brain for the purposes of comprehension and prediction. Cognitive models are developed to study different aspects of cognition; attention and multitasking, judgment and choice in decision-making and skill acquisition in dynamic situations. CARINA metacognitive architecture runs cognitive models. However, CARINA does not currently have mechanisms to store and learn from cognitive models executed in the past. Semantic Knowledge Representation is a field of study which concentrates on using formal symbols to a collection of propositions, objects, object properties and relations among objects. In CARINA Beliefs are a form of represent the Semantic Knowledge, which are elements about facts, concepts or objects. The aim of this chapter is to formally describe a CARINA-based cognitive model through of Denotational Mathematics and to represent these models using a technique of Semantic Knowledge Representation called Beliefs. A CARINA-based cognitive model contains a problem, goals, mental states, beliefs, actions and reasoning rules. All the knowledge received by CARINA is stored in the semantic memory in the form of Beliefs. Thus, a cognitive model represented through beliefs will be ready to be stored in semantic memory of the Metacognitive Architecture CARINA. Finally, we present an illustrative example that describes a cognitive model of a syntactic analyzer for opening questions using beliefs, a structured natural language notation named NGOMS-L and a domain-specific visual language called M++.

Semantic Knowledge Representation is a way of modeling and introduce knowledge using tools that represent notions or concepts (Rajman & Chappelier, 2010) as well as formal symbols in a collection of propositions. Semantic Knowledge Representation is the area of Artificial Intelligence concerned how

DOI: 10.4018/978-1-7998-3479-3.ch005

knowledge can be symbolically manipulated and represented in an automated way by reasoning programs (Levesque, 2004). A cognitive model is a computational model of some internal information processing mechanisms of the brain used in the area of Artificial Intelligence for the purposes of comprehension and prediction (Levesque, 2004). Also, a cognitive model is a theoretically grounded and empirically guided specification of the mental representations and processes involved in a given cognitive function (Zacarias, Magalhaes, Caetano, Pinto, & Tribolet, 2008). Cognitive architectures have been used to create cognitive models of a variety of intelligent systems (Langley, Laird, & Rogers, 2009). A cognitive model of a task constructed in a cognitive architecture is runnable and produces a sequence of behaviors (Cox, Oates, & Perlis, 2011). Cognitive architectures have been used to create cognitive models of a variety of intelligent systems (Forstmann & Wagenmakers, 2015). A cognitive architecture is a general-purpose control system inspired by scientific theories developed to explain cognition in animals and humans (Langley et al., 2009).

A Metacognitive Architecture is a cognitive structure which is able to reasoning about itself (Cox et al., 2011). CARINA is a metacognitive architecture for artificial intelligent agents (Caro et al., 2018). CARINA is derived from the MISM Metacognitive Metamodel (Caro, Josyula, Cox, & Jiménez, 2014). When the reasoner executes a cognitive model in CARINA it is necessary that the cognitive model that was executed be stored in the Semantic Memory in form of beliefs for to be subsequently retrieved. Several researches have presented different ways of Semantic Knowledge Representation in Cognitive Architectures. ACT-R represent the semantic knowledge in units called chunks (Anderson, 1996), SOAR is based on the form of representation of ACT-R, where each chunk collects a number of pieces of environmental information in a single unit (Gobet et al., 2001). CLARION uses various representations according to the type of knowledge used: explicit objective knowledge is symbolic, while implicit procedural knowledge is sub-symbolic (Kotseruba, Gonzalez, & Tsotsos, 2016).

Recent researches on cognitive architectures show some representations of knowledge, for example, Vector LIDA (Snaider & Franklin, 2014) employs high-dimensional vectors. High-dimensional vector spaces have noteworthy properties that make them attractive for representation models (Snaider et al., 2014). These vectors have interesting properties that make them attractive for representations in cognitive models. LEABRA (O'Reilly, Hazy, & Herd, 2015) are based on a purely connectionist model that allows the representation of knowledge. This model represents a worthy explanation of connections for the functional structure and interaction of human attentional networks (H. Wang & Fan, 2007), the early versions of cognitive architectures did not have a powerful semantic memory system that facilitated the development of search processes but rather used relational databases displaying an interface to communication, which made these search processes slower and more complicated. In cognitive architectures the development of cognitive agents requires experts in the language of each architecture to establish the way of representing knowledge and can reason about the world based on a system of semantic memory. The creation of cognitive agents is a difficult task and there is no standardized way to develop them, for that reason, CARINA uses different cognitive approaches such as self-regulation, metacognition and metamemory.

Nowadays it is a difficult and time consuming task to use cognitive architectures for the development of cognitive agents because this type of assignment requires expertise in the own language of that architecture and a very particular knowledge about forms of semantic representation of the architecture. In addition, there is no a systematized way in cognitive sciences neither in computer sciences to design cognitive agents even more if these agents are to perform self-regulation, metacognition and metamemory. The focus of this paper is to present the appropriate Semantic Knowledge Representation of a cognitive model in CARINA. Currently, the metacognitive architecture CARINA executes cognitive

models at the object level using its working memory and it has not mechanisms that allows to store them in its semantic memory. For this reason, the main contribution of this paper is to introduce a new approach for Semantic Knowledge representation of any type of cognitive models which CARINA could be able to execute them using its semantic memory. The CARINA metacognitive architecture requires very particular specifications because it is focused on metacognition, processes of self-regulation and metamemory, which handle chunks and representations commonly used in cognitive architectures that do not take into account the structure of the self-model and the Meta knowledge aspects. This chapter shows the representation of semantic knowledge in the form of beliefs of a cognitive model in metacognitive architecture CARINA. The semantic knowledge in CARINA presents the states in which the system is found. In CARINA Beliefs are information of facts or knowledge that create the Semantic Memory in CARINA. Also, shows an example of the representation of the semantic knowledge of a cognitive model. This chapter is organized as follows: first, a description of the metacognitive architecture CARINA is presented. Then, the structure of a cognitive model in CARINA is formally described using denotational mathematics and the Formal Representation of Semantic Memory Units (SMU) in CARINA. Finally, the implementation and comparison with other cognitive model architectures in CARINA is described.

BACKGROUND

A cognitive model is a computational model of some internal information processing mechanisms of the brain used in the area of Artificial Intelligence for the purposes of comprehension and prediction (Levesque, 2004). Cognitive models are developed to study different aspects of cognition: attention and multitasking, judgment and choice in decision-making and skill acquisition in dynamic situations (Jerónimo, Caro & Gómez, 2018). In the literature has been found different studies about the use of Cognitive Architectures in the Cognitive Models design process as follows: Peebles & Cheng (2002) showed a cognitive model to explain the response time and accuracy of an experiment in which participants' eye movements were stored while various problems were solved with different types of graphs. This cognitive model was based on ACT-R and it allowed to describe a perceptual pattern of ocular fixation by perceptual chunks over time. Thus, fixation patterns were obtained reflecting the limitations of working memory during problem solving. Ritter, Anderson & Koedinger (2007) implemented a cognitive tutor for the mathematics teaching process through the incorporation of a cognitive model in the ACT-R architecture taking as a source of information the learning results, memory and problem solving of the students, with the objective of interpreting the behavior and developing better plans of classes, activities and experiences to learn mathematics.

MacDougall (2016) designs a multi-method approach to model expert cognition in naturalistic environments, based on expert knowledge and existing methodologies for the design of cognitive models. The authors used three methodologies as follows: i) *Macro-SGOMS cognitive model*: This methodology uses theoretical basis of Sociotechnical Goals, Operators, Methods, Selection rules to generate a cognitive model of a cognitive task; ii) *Communication Analysis - Coordination and the division of labor*: This type of methodology was used to enhance the individual SGOMS model to a team model by examining coordination, communication and division of labor in expert communities; iii) *Computational implementation*: In this stage, a implementation in a computer system of the primary points of interest was developed using Python ACT-R for modeling the SGOMS framework, showing team-based coordination units and an interruption mechanism that allowed computational agents to respond without collapsing. Fu & Pirolli (2007) describe a computational cognitive model that explains navigation on the World

Wide Web. The model evaluates the perceived relevance of a web link for a user by using sequential link propagation mechanisms. The model was tested in the ACT-R architecture evaluating the behavior of eight subjects while searching for information on the Internet. The model allowed to dynamically update the evaluation and to decide when to leave a page based on previous experiences providing a good interaction between user and the web.

Nuxoll & Laird (2004) show a Cognitive Model of Episodic Memory Integrated with the SOAR cognitive architecture where the functional steps of the episodic memory to recover the information of facts are described. For this reason general automatic mechanisms are created to remember and to accede to the past to improve the behavior of cognitive agents. Also Mendonca & Wallace (2007) develop a cognitive model implemented in the architecture SOAR for improvisation in emergency situations in which they explain how to act quickly in complex situations, eliminating extensive planning in emergency management and symbolically implementing a theory of cognition in emergency management, based on references to respond to non-planned situations. According to Benjamin, Lyons & Lonsdale (2006), current cognitive architectures for running cognitive models in robotics lack support for concurrence and active perception of environmental elements. For this reason the ADAPT project (Adaptive Dynamics and Active Perception for Thought) is created that is able to model the world as a network of concurrent schemes understanding perception as a problem-solving mechanism, adapting the semantics of natural language to control the actions exercised by the robot. ADAPT was implemented in the SOAR architecture to manage the complexity of its environment and learn new schemes from experience. Kaminka & Fridman (2006) designed a cognitive model of Crowd Behavior Based on the Festinger's Social Comparison Theory (SCT), which explains that people tend to compare their behaviors with others who are more like them. The cognitive model was created for the SOAR cognitive architecture presenting an algorithmic framework which evaluates its implementations in several crowds under a computerized system that when executed individually acts by many agents that behave like humans.

However, the models described above only limited to a numerical or computational description of the most relevant aspects in the resolution of a cognitive task. All these studies, although they use cognitive models in cognitive architectures, do not have a semantic representation that allows them to be stored permanently in the long-term memory of the agent or intelligent system that executes it, for this reason, the work presented here makes an approximation from the description of the fundamental processes that underlying the development of a cognitive computationally task through the formal representation of a cognitive model with the use of denotational mathematics, and additionally shows a semantic representation of a cognitive model described as a result of CARINA metacognitive architecture.

The Semantic Knowledge Representation is a modeling and presenting method of knowledge that uses tools for representing from notions, concepts and formal symbols to collections of propositions (Rajman & Chappelier, 2010). There are several ways to Represent Semantic Knowledge: rules, tables and frames (Tanaka, Aoyama, Sugiura, & Koseki, 1995), Paradigms, facets and Trees (Kwasnik, 1999), ontologies (Chen, Liao, & Prasad, 1998);(Garcia-Crespo, Ruiz-Mezcua, Lopez-Cuadrado, & Gonzalez-Carrasco, 2011), metadata (Matta, Corby, & Prasad, 1998), agents (O'Leary, 1998), Semantic Networks (Peters & Shrobe, 2003);(Miller, 1995), Chunks (Anderson, 1996);(Avery, Kelley, & Davani, 2006), Graphs (Arevalillo-herráez, Arnau, & Marco-giménez, 2013) and neural networks (Zhou, Zhou, He, & Wu, 2016) among others.

In the literature exists different studies that use Semantic Knowledge Representation in Artificial Intelligent Systems. (Peters & Shrobe, 2003) present a semantic network as a way to represent knowledge by constructing intelligent spaces to encapsulate rooms, users, groups, roles and other type of information, which is a fundamental design issue. They use the semantic network structures to capture meetings as

they occur, linking together the main meeting topics along with their contributors and attendees. Given the nature of semantic networks, the addition and change of information are localized and clear, and the generation of inference can be done easily. They are exploring different ways to enrich the interactions the user can provide. They are including a network query language and an activation system. That allows a user to specify a segment of the network that they are looking for, and to receive a notification every time that network element is created.

Other example of most common and widely used semantic knowledge modeling tool is WordNet. WordNet (Miller, 1995) is the resource used to identify shallow semantic features that can be attached to lexical units. (Scott & Matwin, 1998) describes experiments in Machine Learning for text classification using a new representation of text based on WordNet hypernyms that can lead to significant loss in error rates in certain types of text classification tasks. This method uses the lexical and semantic knowledge incorporated in WordNet to move from a bag of words based on hypernym density. The appropriate value for the height of the generalization value depends on the characteristics of each classification task. Another benefit of hypernyms density representation is that the rules are often simpler and more understandable than the rules induced using the word bag.

(Avery et al., 2006) developed the architecture of the Symbolic and Intelligent Robotic Intelligence Control System (SS-RICS). SS-RICS contains production systems, semantic networks, machine learning and sub-symbolic processing to perform the control of the mobile robot in real time. These authors showed the integration of cognitive psychological techniques and artificial intelligence (AI) techniques for allowing to the mobile robots to understand and interacting of a superior way with the dynamic world in which we live. The system was inspired by ACT-R and other computational cognitive architectures that are attempting to merge distributed and symbolic AI approaches. SS-RICS concentrates on using an approach with particular strengths at the right layer in a multi-layered approach. They are leveraging the interaction of different knowledge representation algorithms, more so than they are stressing the use of any particular knowledge representation algorithm.

(Zhou et al., 2016) presents a new perspective to learn the semantic representation of queries and responses in the use of a neural network architecture. The characteristics learned from the semantic level are finally incorporated into a learning framework to classify. The network determines the semantic relation for the query-response pairs. Then, the semantic level characteristics are added in a framework, as well as a set of statistics-based features. The importance of each characteristic in comparison with the rest is learned through a Ranking algorithm. The experiments they did in both the automatic evaluation and the manual evaluation showed a significant improvement in the recovery of questions from the community.

However, in the first versions of cognitive architectures they did not have a powerful semantic memory system that allowed searches, but used relational databases and created an interface to communicate, which made it slower and more complicated. And there was not a Semantic Representation of cognitive models that are executed in those cognitive architectures.

FOCUS OF THE ARTICLE

CARINA Metacognitive Architecture

CARINA is a metacognitive architecture for artificial intelligent agents. CARINA is derived from the MISM Metacognitive Metamodel (Caro et al., 2014). CARINA integrates self-regulation and metamemory with support for the metacognitive mechanisms of introspective monitoring and meta-level control; in

this sense CARINA assumes a functional approach to a mind philosophy, according to (Fodor, 1975), (Piccinini, 2010), (Scheutz, 2001). (Machamer, Darden, & Craver, 2000), the term “mechanism” includes entities and activities involving entities (i.e., including both static and dynamic aspects). The entities in CARINA are called “cognitive elements”. In accordance with MISM, CARINA is composed of three types of cognitive elements: structural elements, functional elements and basic elements. Structural elements are containers into which the functional and basic elements are embedded; the main structural element is the “Cognitive level”. The functional elements are tasks that enable reasoning and decision-making. Basic elements consist of the set of elements that participate and interact in reasoning and meta-reasoning processes. The main functional elements in CARINA are: reasoning task and meta-reasoning task. Reasoning Tasks are actions that enable the processing (transformation, reduction, elaboration, storage and retrieval) of information by applying knowledge and decision making in order to meet the

Figure 1. Structural view of CARINA (own source)

objectives of the system. A Metareasoning Task may be used to explain errors in some reasoning task or it may be used to select between “cognitive algorithms” to perform the reasoning (Raja & Cox, 2011).

CARINA is composed of two cognitive levels named object-level and meta-level. On the one hand, the object-level contains the model that an artificial intelligent agent has for reasoning about the world (i.e. agent’s environment) to solve problems (Caro et al., 2018). Object-level behavior consists of cognitive functions such as problem solving or memory retrieval (Cox, 2005). In CARINA, object-level has stages which are sets of cognitive functions (CF), (See Figure 1), Perception Stage (perception CF), Situation Assessment Stage (Situation Assessment CF, Categorization CF, and Recognition CF), Reasoning Stage (Reasoning CF, Belief Maintenance CF, and Decision Making CF), Problem Solving Stage (Planning CF, Prediction CF), Interaction Stage (Interaction CF, Communication CF) and Action Stage (Action CF). In this object-level the cognitive models designed by cognitive modeler are executed. In CARINA, the cognitive model must be loaded in its working memory each time that is wanted running it. This occurs due to that CARINA does not have a mechanism to store the cognitive models that have already been executed in it.

On the other hand, the meta-level contains a dynamic model of the object-level (Cox, 2005). The meta-level includes the components, knowledge and mechanisms necessary for a system to monitor and control its own learning and reasoning processes.

The reasoning process in CARINA takes as input beliefs, assumptions and expectations. It then reaches some mental conclusion (e.g. categorization). This is a central cognitive activity that enables an agent to augment its knowledge state. The problem solving process is closely related to reasoning in the sense that it is given a goal (in the world or within the agent) and the agent then chooses and orders its actions to achieve this goal. Monitoring a plan’s execution can also lead to revised estimates about the plan’s effectiveness, and, ultimately, to a decision to pursue some other course of action. In CARINA, decisions are often associated with the recognition of a situation or pattern, and combine the two mechanisms in a recognized- act cycle that underlies all cognitive behavior. Finally, acting involves the representation and storage of motor skills that enable the activities stored in Procedural Memory.

Formal Representation of Cognitive Model in CARINA

According to Jerónimo et al., (2018) a cognitive models are established to explore various areas of cognition; attention and multitasking, judgment and choice in decision making and skill building in dynamic conditions (Gonzalez, 2002). Cognitive architectures have been utilized to developed cognitive models of a range of intelligent systems (Forstmann & Wagenmakers, 2015). A cognitive model of a task built in a cognitive architecture is runnable and provide a string of conducts (Byrne, 2003).

Here officially a cognitive model in CARINA expending items of denotational mathematics suggested by (Wang, 2015) is described. A cognitive model consists of declarative knowledge, that indicate facts, also a procedural knowledge indicating reasoning rules. In addition modeling how to reason, as well necessary to model the control on when to reason about what (Muller & Heuvelink, 2008)

Let a CM cognitive model in CARINA, with:

$$CM \triangleq (P, G, S, MS, PK, SK)$$

Where:

p is the problem to solve utilizing CARINA.

$g \in G$, where g is a goal. A goal is an aim the system under consideration should obtain
 $s \in S$, where S is a Sensor. A sensor has the role of inspect the profiles of cognitive tasks to detect irregularity that may exemplify reasoning failures occasioned by the cognitive task (Caro et al., 2014).
 $m \in MS$, where MS is a mental state. Mental state is a Booleans variable that could be right or wrong. A state of mind is a state in which an agent is found.
 PK , represents the procedural knowledge that the system needs to perform the cognitive task, this is how process knowledge is formed in CARINA.

Let: $r \in R$, r is a production rule, with

$r \in (\text{condition}, \text{conclusion})$

With

$\text{condition} \triangleq (AS, C)$

With

AS is a sequence of variables, used to execute rules that fire the rules established in the cognitive task, in this sense a rule r is fires if there is a complete match with AS variables

$c \in C$ and $c \neq C$ and $c \neq AS$

c represent an additional limitation appended by cognitive developer.

A constraint (c) is a particular condition to match, in some conditions $c = \{ \}$

C are the conclusions. Conclusions are the actions triggers when the rule (c) are fires

In this context $a \in A$, with a is an action.

SK is a Semantic Knowledge. The Semantic Knowledge is the knowledge necessary to conduct the cognitive task. Semantic Knowledge is a group of beliefs archive in semantic memory for recovery over reasoning process.

Let: $f \in F$ with f is a Field. Where

$FD \subset F \wedge FB \subset F$

And F is a set of attributes of a SMU

A SMU is the Semantic Memory Unit, which semantic memory is composed by:

FD are primitive group of data type like as string, integer.

FB are collections that aim to a Beliefs of semantic memory.

And β are the Beliefs. The beliefs are clear epistemic atoms that depict declarative knowledge (Pezzulo & Calvi, 2004). According to (Rao & Georgeff, 1991) beliefs get and store information generated by the environment. Beliefs in CARINA architecture are the items of declarative knowledge, thus, information based on events that are stored. So beliefs represent the minimum unit that structures semantic memory in CARINA architecture (Caro et al., 2018).

The cognitive models in CARINA start with the specification of the problem to solve. In the sum of two numbers, the problem has three fields that CARINA must obtain. CARINA can get information of the problem from the sensors, estimating or recovering the information from the long-term memory.

```
1 "PROBLEMS": {
2 "TYPE": "ADDITION-SINGLE-COL-PRO",
3 "ADDENDUM_1": "EMPTY",
4 "ADDENDUM_2": "EMPTY",
5 "SUM": "EMPTY"
6 }
```

When CARINA reads a problem, then it creates a problem space. For each problem space, CARINA inserts a group of mental states that enable it to have updated information about the current state of the missing information to solve the current problem.

```
1 "MENTALSTATES": {
2 "PROBLEM_IS_INITIALIZED": FALSE,
3 "ADDENDUM_1_IS_READ": FALSE,
4 "ADDENDUM_2_IS_READ": FALSE,
5 "SUM_IS_CALCULATED": FALSE,
6 "SUM_FACT_IS_SAVED": FALSE,
7 "SUM_IS_DISPLAYED": FALSE,
8 "PROBLEM_IS_DONE": FALSE
9 }
```

CARINA can create goals using the mental states of the problem space. Every goal is directed to reach shifts in one or some mental states. A goal has posited both the current value of the current mental state and the expected value after goal method execution. The following two code fragments shown an example of the knowledge composition that save a goal in CARINA. For example, goal g701 points to modify the addendum_1_is_read mental state. When the goal is obtained the internal state changes from False to True. In CARINA, the group of goals that the system generates within the current problem space is named Motivational System.

```
1 "G701": {
2 "MENTAL_STATE": "ADDENDUM_1_IS_READ",
3 "CURRENT_VALUE": FALSE,
4 "TARGET_VALUE": TRUE
5 }
```

A group of production rules and an inventory of available cognitive functions represents the procedural memory of CARINA. In this code fragment a production rule is displayed.

```
1 "RULE702": {
2 "CONDITION": {
3 "ATTENTION_SYSTEM": {
```

```

4 "PROBLEM": "P2",
5 "MENTAL_STATE": "ADDENDUM_2_IS_READ",
6 "GOAL": "G702",
7 "SENSOR": "SENSOR1"
8 },
9 "CONSTRAINT": {}
10 },
11 "CONCLUSION": {
12 "ACTION1": {
13 "NAME": "READNUMBERFROMPERCEPTOR",
14 "COMPLETE": FALSE
15 },
16 "ACTION3":{
17 "NAME": "NEXTGOAL",
18 "ARG": {
19 "GOAL": "G703"
20 },
21 "COMPLETE": FALSE
22 }
23 }
24 }

```

Fragment 1 includes the name of the rule that is a unique identifier. The condition part of the rule encoded from fragment 2 to 8. The condition includes the variables of the attention system that are important for the rule to be triggered in the context of the current problem.

The conclusion part of the rule covers lines 11 to 23. This fragment shows the order in which the basic cognitive functions of CARINA must be implemented. Fragment 12 and 16 show the calls to two functions `readNumberFromPerceptor` and `nextGoal`.

A cognitive model also includes semantic knowledge in the form of Beliefs. In the cognitive model, the Beliefs essential for CARINA to resolve problems in a knowledge dominance are specified. In the following extract of code the basic structure of a belief that represents the number 1 in the problem of the sum of two numbers is described.

```

1 "ONE": {
2 "TYPESMU ": "NUMBER",
3 "HAS": {
4 "TYPE": "INTEGER",
5 "VALUE": "1",
6 }
7 }

```

Comparison with Other Cognitive Architectures

This part explains the similarities and differences among the implementation of cognitive models in CARINA and ACT-R. ACT-R was used for analogy due to its disclosure and extensive number of published cognitive models. For the comparison, the model explained in paper (Lebiere, 1999) was taken.

Similarities

In ACT-R, declarative knowledge is described in the form of “chunks”, which are singly a set of key-value pairs. In CARINA, beliefs are utilized in the similarity of chunks. The difference is the internal structure of each one, since the beliefs of CARINA have two sections with two relationships: IS-A and HAS. The procedural knowledge in CARINA and ACT-R is represented in the form of production rules, although they do not have the same structure, they execute comparatively equal.

Differences

The definition of a problem in CARINA has a particular specialized structure, while in ACT-R the problem is described in the condition of one or more production rules, as shown in the example below.

```
1 (P INITIALIZE-ADDITION
2 =GOAL>
3 ISA ADD
4 ARG1 =NUM1
5 ARG2 =NUM2
6 SUM NIL
7 ==>
```

CARINA in addition to having production rules can have specialized algorithms that in a more granular form are triggered by the production rules.

Formal Representation of Semantic Memory Units (SMU) in CARINA

Cognitive agents must have the ability to represent knowledge, learn and reason which remain as research challenges in the area of agent world (Nwana & Ndumu, 1999). All the knowledge received by CARINA is stored in the semantic memory in the form of beliefs. The nodes found in the beliefs network refer to the semantic memory units (SMU), and links refer to the various relations between these units (Shi, Zhou, & Wang, 1997).

$\beta = \langle \text{ISA}, \text{HAS} \rangle$

Where $\beta \in B$ and β is a set of SMU, with:

ISA is a set of fields, where $f \in \text{ISA} \wedge f \in B \wedge \text{ISA} \neq \{\}$

HAS is a set of fields, where $f \in \text{HAS} \wedge f \in B \wedge f$ is a basic data type.

In formulae (4) β is a SMU that is the minimum unit of information contained in the semantic memory of a CARINA-based cognitive agent. According to (Shi et al., 1997) Semantic units are those components that are extracted from knowledge after it is “computed”. The set of fields C represent relationships of a hierarchical type between the SMU. A SMU can have one or several ISA fields; therefore it is necessary to know the context of each SMU for the disambiguation of the semantic relations within the declarative memory. The set of HAS fields can represent aggregation relationships (i.e. is-part-of links) or descriptive field relationships (qualities and characteristics of a concept).

Beliefs are explicit epistemic atoms that represent declarative knowledge. In CARINA, the basic units of representation of knowledge are beliefs; the beliefs are elements of declarative knowledge about facts, concepts or notions from the world and from same cognitive agent (Apt, Blair, & Walker, 1988). Beliefs constitutes the minimum unit of semantic memory.

According to the above, each Belief is structured into two essential parts: i) ISA: that specifies the category which belongs to this belief (and that points to another belief that is stored in the semantic memory); ii) HAS: which specifies the other fields that characterize this belief in particular. In the following fragment of code the basic structure of a belief that represents the number 1 in the problem of the sum of two is shown.

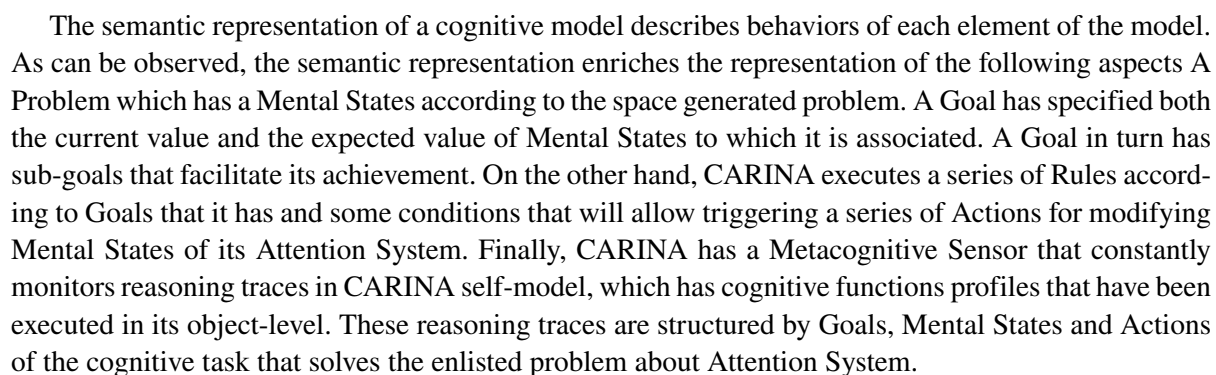

```

1 "one":{
2 "isa":{
3 "number"
4 }
5 "has": {
6 "type": "integer",
7 "value": "1",
8 }
9 }
```

Semantic Knowledge Representation of a Cognitive Model in CARINA

The Metacognitive Architecture CARINA executes cognitive models in the object level using its working memory. This cognitive models must be loaded each time that running them is wanted. CARINA has not mechanisms that allow store them it in its semantic memory. For this reason, it is necessary to semantically represent a cognitive model because after its execution, it can be stored in the semantic memory of CARINA and thus CARINA can execute it later on without direct supervision of cognitive designer. Thereby, the semantic representation of a cognitive model executed in the Metacognitive architecture CARINA is presented. This representation is made through of beliefs in Semantic Memory of CARINA, allowing thus a greater facility in designing the future learning processes of this Architecture. Taking into account theoretical assumptions of (Brachman & Schmolze, 1988), the semantic representation of a cognitive model in CARINA is useful due to fact that when it is represented symbolically, can be manipulated in an unsupervised way by the semantic memory of CARINA. Thus providing CARINA with the necessary foundations for the development of learning mechanisms that allow it to retrieve from its semantic memory each and every one of the cognitive models that have already been executed by it.

For this research we have represented these cognitive model elements (Problem, Goal, Sensor, Mental State, Procedural Knowledge and Semantic Knowledge) through of a Beliefs Map (See Figure 2).

The problem discussed in this chapter is the semantic representation of cognitive models executed in CARINA that allows store them in its long-term memory. For this reason is recommended develop learning mechanisms that facilitate the reusability and modularity of the constitutive elements of cognitive models. CARINA must be able to create its own cognitive models in an automatic way and it must have to a forgetting function that allow to liberate memory with repeated elements among cognitive models

FUTURE RESEARCH DIRECTIONS

In this work it is necessary to continue working on the representation of knowledge through the meta-cognitive architecture CARINA, for this reason:

- 1- CARINA must have a learning mechanism that allows it to compare the stored cognitive models, in addition must be able to save the necessary information from a cognitive model, such as: problem, goals, mental states, beliefs, actions and reasoning rules to solve and execute new cognitive tasks of the environment based on its previous learning.
- 2- Based on the stored cognitive models, CARINA must be able to create its own cognitive models to solve cognitive tasks in any environment.
- 3- CARINA must have a forgetting function for cognitive models that allows it to delete unnecessary information and optimize the algorithms that are executed.

This technology can be used for the development of information systems that automates tasks executed by human agents in organizational knowledge management processes using production rules. This computational systems that use cognitive models to simulate specific tasks in an organization, will allow in the future the development of intelligent agents that facilitate the execution of organizational processes in a most efficient and effective way in any type of environment.

CONCLUSION

In this chapter was presented a method for Represent Semantically a CARINA based cognitive model, this technique was called Beliefs. CARINA is a metacognitive architecture for artificial intelligence that was derived from the MISM Metacognitive Metamodel. The composition of a cognitive model was shown using denotational mathematics. A CARINA-based cognitive model includes the specification of a problem (cognitive task), a series of mental states that shows an initial state and a desired state, a series of goals, procedural knowledge and semantic knowledge. The cognitive task of adding two numbers, was used as an example, in which mental states, goals, rules of production and beliefs are described in detail. All the information received by CARINA is stored in the semantic memory in the form of beliefs. Therefore, all kinds of cognitive models represented through beliefs will be ready to be stored in the semantic memory of the metacognitive architecture CARINA. Carina has a representation in the memory of different types of structures of the cognitive model, in the form of beliefs. In this way CARINA in a near future, can autonomously generate a new complete cognitive model.

KEY TERMS AND DEFINITIONS

Beliefs: Beliefs are a form of represent the semantic knowledge, which are elements about facts, concepts, or objects.

Cognitive Architecture: A cognitive architecture is a general framework for specifying computational behavioral models of human cognitive performance.

Cognitive Model: A cognitive model is a computational model of internal information processing mechanisms of the brain for the purposes of comprehension and prediction.

Denotational Mathematics: Is an abstract structure that uses exclusive semantics in almost all cognitive actions like those of thinking, knowledge representation, learning, and reasoning.

Metacognitive Architecture CARINA: CARINA is a metacognitive architecture for artificial intelligent agents. CARINA is derived from the MISM

Semantic Knowledge Representation: Semantic knowledge representation is a field of study which concentrates on using formal symbols to a collection of propositions, objects, object properties and relations among objects.

Semantic Memory: Semantic memory incorporates all achieved knowledge about the world, not contextualized in time and space.

Error Types in Natural Language Processing in Inflectional Languages

INTRODUCTION

Natural Language Processing is the area of research that explores how humans can interact with computers in natural language. It is a subfield of Artificial Intelligence. The development of NLP applications is a challenging task, as natural languages are ambiguous, and not structured as strictly as programming languages, which were developed for the purpose of human-computer interaction. Today, we are faced with large amounts of data, available on the internet. The development of Natural Language Processing applications provides invaluable insight into very diverse data sources, which are not manageable by humans, but by the use of technology.

There are many different tasks in Natural Language Processing. To cover all of them within this article would be impossible. This article focuses only on two prominent Natural Language Processing applications: Automatic speech recognition and machine translation. The task of automatic speech recognition is for a machine to recognise the spoken words from an audio signal. This can be done on pre-recorded speech or live from a microphone. Essentially, it is the conversion from speech to text. The application area of automatic speech recognition is very broad. For example, it can be used for subtitling TV programmes for deaf people. Machine translation is the task of translating some text from one natural language to another. It can be applied to catch the meaning of a text written in a language that the reader does not understand.

The effectiveness of Natural Language Processing methods varies greatly, depending on the language under consideration. Highly inflected languages belong to a group of the most difficult languages to process. This article deals with one representative of this group, Slovene. It is a morphologically rich language with complex grammar, which harms the performance of Natural Language Processing tasks. The motivation of this article is to analyse errors that result from the characteristics of Slovene, and are not so frequent in Natural Language Processing of other languages.

BACKGROUND

Natural Language Processing

Large amounts of data are being created online every day, and many data are in the form of text in a natural language. The idea is to process and examine the data and to uncover new knowledge. Computers know how to process structured data, but data in natural language is unstructured. It requires specialised

DOI: 10.4018/978-1-7998-3479-3.ch006

approaches to process it. The research field that copes with this phenomenon is called Natural Language Processing.

Natural Language Processing (NLP) is a sub-field of Artificial Intelligence. It focuses on enabling computers to understand and process natural languages as humans do. Although NLP research has a long history, many problems are still unsolved. Computers are far behind human abilities. We still do not know precisely how humans process language. Despite that, today, computers offer many, quite useful applications that are based on natural language. The machine learning evolution spurred remarkable technology breakthroughs. NLP evolved from a time-consuming process where rules were handwritten by humans, to unsupervised learning, where computers learn from data by themselves.

There are many interesting tasks which are based on NLP:

- Document summarization: Automatically generating synopses of large bodies of text.
- Automatic speech recognition: Transforming voice into written text.
- Speech synthesis: Transforming text into voice.
- Machine translation: Automatic translation of a text (or speech) from one language to another.
- Sentiment analysis: Identifying the emotions and subjective opinions within large amounts of text.
- Semantic analysis: Interpreting human sentences logically.
- Natural language understanding: Transforming the meaning of a text into a structured semantic form.
- Natural language generation: Generating text from structured data in a readable format with meaningful phrases and sentences.
- Question Answering: Generating answers to questions in the form of a sentence. It is based on natural language understanding.
- Dialogue systems with virtual assistants: Using natural dialogue that mimics a live agent interaction.

Every day, new ideas for applying NLP arise. The goal of almost all NLP tasks is to take raw language input (in written or spoken form) and use linguistic knowledge and algorithms to deliver higher value to the user.

In the continuation of this article we will focus on two NLP tasks: Automatic Speech Recognition and Machine Translation.

Automatic Speech Recognition

The most natural, and also essential, form of human interaction is by speech. In the modern world, however, more and more of our interaction is not only with other people, but with information systems. In the pursuit of a natural interaction between humans and machines, Automatic Speech Recognition (ASR) systems have been developed for the better part of the 20th century in order to be complementary with traditional methods of human-computer interaction, e.g., keyboards and graphical user interfaces. Today, the advancement of speech recognition can already be observed in commercial applications, such as home assistants.

Other applications of ASR may be the transcription of spoken dialogue into text form for the hearing impaired and speech to speech translation, where speech recognition is performed first, then machine translation, and then speech synthesis, in order to enable spoken interaction between people who do not speak the same language.

The vocabulary of an ASR system determines the set of words that can be recognised. Given the target application, vocabularies can have a size of several words to a few hundreds of thousands of words.

Simple speech recognition systems are able to recognise only a limited number of words spoken in an isolated manner, i.e., with pauses between words, while more complex systems can recognise words from a much larger vocabulary that are spoken continuously as a sentence.

In the process of speech recognition, firstly mel-frequency cepstral coefficients, or perceptual linear coefficients, are used typically for the extraction of relevant acoustic information from the audio signal in the form of features. Hidden Markov models are then used for acoustic modelling of phonemes and, sometimes, in systems with a limited vocabulary, modelling of whole words. Additionally, phonemic dictionaries are necessary to recognise words from a set of recognised phonemes. In such systems, only isolated words or phrases can be recognised.

In systems where continuous speech, i.e., naturally spoken sentences, are to be recognised, some kind of language model is necessary. In more limited systems, this can be achieved using regular grammar. This kind of language model is built by determining manually rules that describe allowed word sequences, and is implemented in the speech recognition system by the developers. This is feasible in more limited applications, designed for a limited number of usage scenarios.

Statistical language models are used for speech recognition in a more general domain. Those are built using appropriate tools from large training corpora, i.e., large collections of written texts. Statistical language models determine the probability that a given sentence or sequence of words might occur in the given language. Language models are not perfect, as they may assign a very low probability to sentences which happen not to occur in the training corpus. Also, as large corpora consist of written text, language models perform rather poorly while trying to model spontaneous speech, where a speaker might repeat or omit a word or correct themselves.

There are different challenges in different application areas of ASR. The first challenge is an accurate recognition of the spoken words. The accuracy of speech recognition systems is dependent greatly on the usage domain, the vocabulary size, the spontaneity of speech and the presence of background sounds.

How good is speech recognition? By far the most well-established metric for the evaluation of speech recognition systems is the Word Error Rate (WER). It is defined as the ratio between the number of (word level) errors and the total number of words in the correct sentence or speech segment which was processed by the system. There are three main types of errors: The deletion of a word, where the output of the system is missing a word; the insertion of a word, where a not spoken word appears in the system output; and the substitution error, where the system misrecognises a word for another. The Word Error Rate is determined using the so-called edit distance or Levenshtein distance, and is usually presented as a percentage. The value range for the Word Error Rate is from 0% upwards, and can, in extreme cases, even exceed 100% if there are more errors than actual words spoken. This would be possible if enough wrong words were inserted. Alternatively, the performance of an ASR system can be expressed with the accuracy which is calculated simply as the difference between 100% and the Word Error Rate percentage. A perfect speech recognition system has a Word Error Rate of 0%, or an accuracy of 100%.

Machine Translation

Language diversity in the world triggered the idea of Machine Translation to ‘overcome language barriers. To mention an example, the EU has 24 official languages, and it is very likely that one is confronted with a text in a language that he/she does not understand. Machine Translation (MT) is the automatic translation of a text, written in natural language, by a computer programme, with no human involvement.

The goals of the first MT systems were mainly to bring the meaning of some text to the reader who does not understand the language in which the text is written. Although today the goals of MT are set much higher, the primary goal is not always reached. We still do not have the warranty that the meaning of the source text is preserved in Machine Translation.

Human translation, however, often has a more ambitious aim, to produce texts that satisfy the linguistic norms of the target culture and are adapted to the assumed knowledge of its readers. From this perspective, MT will never supersede human translation. The research has shown that MT can produce human-like translations only in very restricted domains.

The first MT systems were rule-based systems. They appeared in the early fifties. Translation rules were created by experts of linguistics. The process was costly, and the rules were often not general enough to be applicable to other languages. Even for a predefined language pair, the sets of rules were hard to maintain and update. The first results of MT were very promising.

The idea of introducing statistics into Machine Translation has been studied since the early 1990s. Statistical MT (SMT) learns statistical dependencies from parallel and monolingual corpora. No linguistic knowledge is needed in the process of MT system building. Generally, SMT systems are not tailored to any specific pair of languages. To build an SMT system for a given language pair, only parallel corpora for that pair of languages is needed. If available, a monolingual corpus of the target language text can improve the fluency of Machine Translation. Translations in most successful SMT systems are based on phrases, defined by a data-driven process. An SMT system consists of many sub-components, each responsible for a specific part of the translation process, for example: For phrase translation; for reordering; for making the output a fluent sequence of words, etc. For a long time, SMT was by far the most widely studied Machine Translation method.

Neural Machine Translation (NMT) is the newest method of MT. The first experiments have shown its ability to create translations of higher quality than SMT. Unlike the traditional phrase-based translation system, which consists of many sub-components that are used as independent models, Neural Machine Translation attempts to build and train a single, large neural network that reads a source sentence and outputs a translation. Recurrent neural networks organised into an encoder-decoder architecture are used frequently. This architecture allows the variable length of source and target sentences as is common in translation.

How good is the Machine Translation? The evaluation of MT is not needed only to judge the translations of one system, but also to compare different MT systems, and to track the progress during the MT system building. Various methods for the evaluation for Machine Translation have been employed. Most reliable is the human evaluation, but it is costly and time-consuming. The automatic evaluation is an alternative. It is based on the correspondence between the MT output and reference translation (gold standard). Many evaluation metrics were defined by the research community. BLEU (Papineni et al., 2002), METEOR (Denkowski and Lavie, 2014) and TER (Snover, Dorr, Schwartz, Micciulla, & Makhoul, 2006) are the most widely used. BLEU (Bilingual Evaluation Understudy) is the most commonly used evaluation metric. It measures the overlap of unigrams (single words) and high order n-grams between MT output and reference translations.

MT usually contains errors. Some of them can be fixed very easily. Because of that, the combination of MT with human post-editing of errors has become an appealing solution (Moorkens & O'Brien, 2015). It has been shown that post-editing MT can be faster than producing translations from scratch manually. It depends on the quality of translations produced by an MT system.

Inflectional Languages

The defining characteristic of inflectional languages is the use of an inflectional morpheme in its words to denote several of its grammatical features. Those can be tense, case, person, number among others. Word inflections are also present in non-inflectional languages. For example, in English, the suffix ‘-s’ is used to express nouns in plural form and the suffix ‘-ed’ to express verbs in the past tense. However, the degree of inflection in English is much smaller than in inflectional languages.

Examples of highly inflectional languages are Slavic languages. For instance, in Slovene, the verb ‘biti’ (to be) has 39 different forms. Other Slavic languages are Czech, Slovak, Polish, Russian, Ukrainian, Croatian, and Serbian, among others.

The rich morphology of inflectional languages results in greater challenges for NLP application. One simple factor is the high number of word forms, resulting in the need for larger vocabularies. For speech recognition, this results in a high number of acoustically similar words, that could be misrecognised. Another factor is a freer word order, which is problematic for Machine Translation, as the same meaning with the same words can be expressed differently. In both applications, the large number of words in the vocabulary causes a need for even greater training corpora for building language models.

Table 1 and Figure 1 show examples of the properties of words and sentences in Slovene. In Table 1 we see the noun ‘besedilo’ (text) in all 6 cases and three numbers of Slovene. The word has eight possible endings (including no ending in the form ‘besedil’). Additionally, the verb ‘besediti’ (to text, to put into words) has the same root and similar word forms as the noun. The verb has 16 different forms, of which some are the same as for the noun. As some word forms are still the same, their exact part of speech and morphological properties can only be determined by looking their context (the entire sentence).

Table 1. The word ‘besedilo’ (text) in all 6 cases and 3 numbers of Slovene

Case	Singular	Dual	Plural
Nominative	besedilo	besedili	besedila
Genitive	besedila	besedil	besedil
Dative	besedilu	besediloma	besedilom
Accusative	besedilo	besedili	besedila
Locative	besedilu	besedilih	besedilih
Instrumental	besedilom	besediloma	besedili

Figure 1 shows the example of a sentence in 2 different forms with different words orders. In the first example, the verb ‘je napisal’ (wrote) is before the subject ‘besedilo’ (the text), while in example 2, the subject is before the verb. Both sentences are grammatically correct and are also stylistically acceptable, while in English the sentence ‘The text he wrote today’ is not.

Figure 1. An example of the free word order in Slovene with 2 sentences with the same meaning and their English translation

Example 1: Danes je napisal besedilo.	(word order: verb, subject)
Example 2: Danes je besedilo napisal.	(word order: subject, verb)
English: He wrote the text today.	

We can also see that the Slovene word ‘danes’ (today) is at the start of the sentence, while its translation to English is at the end of the sentence.

Also the verb ‘je napisal’ is in the 3rd person masculine form, meaning that the Slovene examples do not need a pronoun to make the meaning of the sentence clear, while the English translation needs the pronoun ‘he’.

CLASSIFICATION OF ERRORS IN NLP APPLICATIONS

Identification of errors is an important step in every language-processing task. If we detect errors and analyse them, we can, consequently, improve the core procedures of the language processing task, or add an additional post-processing step in which we correct errors. In the continuation of the chapter, we focus on error analysis in ASR and MT.

Errors in Speech Recognition

The basic error types in Automatic Speech Recognition are deletion, insertion, and substitution. The Word Error Rate (WER) is calculated using the equation:

$$WER = \frac{D + I + S}{N} \cdot 100\%.$$

where D is the number of deleted words, I is the number of inserted words, S is the number of substituted words, and N is the number of all words in the correct transcription.

Figure 2 shows examples of all three basic error types, where LAB denotes the reference transcription, i.e., the correct spoken sentence, and REC denotes the speech recognition output. In Figure 2.a the word ‘je’ is missing in the recognition output, thus representing a deletion error. Similarly, in Figure 2.b the word ‘sicer’ is an insertion error, and, in Figure 2.c, the mismatch of the words ‘droge’ and ‘drugi’ is a substitution error.

Figure 2. Examples of the three basic error types in speech recognition, (a) A deletion error, (b) An insertion error, and (c) A substitution error

- a)
- | |
|--|
| LAB: naša ekipa pa si je razmere ogledala v dobu in se na lastne oči |
| REC: naša ekipa pa si razmere ogledala v dobu in se na lastne oči |
- b)
- | |
|---------------------------------------|
| LAB: imela drugi prosti program |
| REC: imela sicer drugi prosti program |
- c)
- | |
|--|
| LAB: povedala nam je da droge ne uživa že osem mesecev in se pri tem |
| REC: povedala nam je da drugi ne uživa že osem mesecev in se pri tem |

The causes of recognition errors can be diverse. They can be caused by acoustic factors, the speaker, language factors, the limited vocabulary, or the spontaneous nature of speech.

Furui, Nakamura, Ichiba and Ichiba (2005) examined the effects of spontaneous speech on speech recognition results. Adda-Decker and Lamel (2005) showed that speech recognition for male speakers had a higher error rate than for female speakers. Various authors have also shown that error rate increases with fast or very slow speech, as well as for infrequent words (Fosler-Lussier & Morgan, 1999, Shinozaki & Shinozaki, 2001).

Goldwater, Jurafski and Manning (2010) describe several factors that contribute to error rates of certain words. These can be disfluency factors, such as fragments and repetitions, or prosodic characteristics, such as pitch, intensity, duration, and jitter. They also describe double confusable pairs, which consist of words that are not only acoustically similar, but also have similar probabilities in the language model.

The confusion of acoustically similar words is very present in inflective languages, where the inflection results in several word forms, which, typically, differ in the word ending. This increases the required number of words in a vocabulary that would cover the language sufficiently. It is estimated that, for inflectional languages, the vocabulary size should increase by a factor of 10 compared to an English vocabulary in order to cover the same amount of the language. While using smaller vocabularies, a certain percentage of error is unavoidable, as spoken words are not in the vocabulary. Increasing the vocabulary size, therefore, reduces the error rate. However, increasing the vocabulary size results in large language models and the need for a larger training corpus (Donaj & Kačič, 2017, Nouza, Nejedlova, Zdansky, & Kolorenc, 2004).

Rotovnik, Sepesy Maučec, and Kačič (2007), dealt with the problem of vocabulary size by using subword based models, where words were split into the stems and the endings. While a small decrease in Word Error Rate was observed, the resulting language models and search algorithm were more complicated.

Donaj and Kačič (2017) have presented a classification of errors in an inflective language based on lexical features. They have found that approximately 10% of errors are due to a falsely recognised ending, resulting in a substitution error, where both words in the substitution pair have the same lemma. Similar errors in the word ending can appear, where the lemma is also changed, e.g., a substitution of adjectives and adverbs with the same word root. They also found that short words, including pronouns, prepositions and conjunctions, numerals, and proper names, have higher error rates. The highest error rate was observed with proper names.

Errors in Machine Translation

Errors in MT differ from errors in ASR. In speech recognition, words are recognised one after another, and in this process, because of miss-recognition, some words are omitted, substituted by acoustically similar words, or inserted. In the translation process different phenomena can be found. In a correct translation words often change their place in an output sentence (see the word ‘danes/today’ in Figure 1); the same word could be translated to different words, depending on the context; some words should be omitted or inserted in some contexts. All these events cause errors when a machine performs the translation. Especially in statistical MT, where translations are learned from large parallel corpora by discovering statistical relationships between words, specific errors are hard to predict and fix.

BLEU, the most used metric for the evaluation of MT, is calculated by the following formula:

$$BLEU = BP \cdot \exp \left(\sum_{n=1}^N w_n \cdot \log p_n \right).$$

where p_n is n-gram precision, and w_n is a positive weight. All weights sum to 1. N is the maximum order of n-grams. It is commonly set to 4. BP denotes the brevity penalty factor. With this brevity penalty in place, a high-scoring candidate translation must now match the reference translations in length. The brevity penalty is 1.0 when the candidate's length is the same as reference translation's length. Scores, between 0 and 100 (perfect match), are then averaged over the whole set of sentences selected for evaluation, to reach an estimate of the translation's overall quality.

METEOR (Metric for Evaluation of Translation with Explicit ORdering) is based on the harmonic mean of precision and recall, whereby recall is weighted higher than precision. METEOR has additional features, i.e., stemming, paraphrasing and synonym matching.

TER (Translation Edit Rate) is a derivate from the WER. It uses an additional edit step, namely shifts of word sequences. A shift moves a contiguous sequence of words within the evaluated translation to another location within the translation. In TER all edits have equal cost. Although much effort has been invested in the automatic evaluation of MT, it is still difficult to trace the improvements in the MT system by computing the values of evaluation metrics. It is also difficult to say which MT system is better than others, based solely on values given by evaluation metrics. Even if a metric correlates well with human evaluation in one study on one evaluation set, this correlation may not carry over to other evaluation sets. Manual inspection is always beneficial.

It is important to know that some errors could happen in any Machine Translation task regardless the languages in translation. On the other hand, there are errors that occur in one language and not in another. In the continuation of the chapter, we focus on translation errors that appear if we translate between English and the highly inflected Slovenian language.

The most frequents issues when translating to and from Slovene are (Popović & Arčan, 2015):

- Multi-word expressions: Multi-word expressions consist of a head noun and additional nouns and adjectives. Multi-word expressions in English are frequently translated to unintelligible sequences of words.
- Negation: In English, negative clauses and sentences commonly include the negative particle not or other negative words, like no, nothing, never, etc. On the contrary, Slovene conventionally employs double negatives, where a negation is added to the verb and to the noun. Because of that, negation structures are translated incorrectly.
- Word order: If phrase boundaries are not detected correctly, words in translation are misplaced.
- Prepositions: There are hardly any rules as to when to use which preposition in English. A 1:1 translation to/from Slovene is usually not possible. One preposition in Slovene might have several translations in English, depending on the situation. Therefore, prepositions are frequently mis-translated, omitted or added.

Some translation errors depend on translation direction. The most frequents issues when translating to English are (Popović & Arčan, 2015):

- Articles: In Slovene, articles are not used. Because of that, some articles in English translation are missing.

- **Pronoun:** In some cases in Slovene, pronouns could be omitted. Therefore, several pronouns are missing in the English translation. The Slovene pronoun 'svoj' can be used for all persons, and it is difficult to disambiguate for translation in English.
- **Tenses:** The tense system in English differs to a great extent from tense systems in Slovene. Frequently, the tense from the source language is preserved and causes mistranslation.

For translation from English to Slovene, the problem is that, in the source sentence, much information is missing to generate rich morphology in translation. The most frequent errors are:

- **Case:** An incorrect case is used.
- **Adjective-noun agreement.** All Slovene adjectives must agree with nouns in number, gender, and case. Often incorrect cases appear in combination with incorrect number or gender agreements
- **Verb inflection:** Verb inflection does not correspond to the person, as in English there are only two verb inflections regarding the person. For a similar reason, sometimes, verb inflection does not correspond to the tense.
- **Noun-verb disambiguation:** There are a number of English words which can be used both as a noun as well as a verb. On the contrary, in Slovene, different words are used for nouns and for verbs. Sometimes it is difficult to disambiguate, and wrong words are chosen.

Error identification is not always a straightforward task. Sometimes errors are difficult to localise. Some errors are diffused across the sentence, or even a larger unit. Some examples of translation errors are collected in Table 2, while a more complete classification is given in Figure 3.

Table 2. Examples of MT errors

Error type	Sentence
Source sentence (English)	Being a rector does not give someone the freedom
Correct translation (Slovene)	Biti rektor nikomur ne daje svobode
Negation	Biti rektor ne daje <u>nekaj</u> svobode
Wrong case	Biti rektor nikomur ne daje svoboda
Wrong word order	Biti rektor nikomur ne <u>svobode daje</u>

Figure 3. Classification of error types in MT

SOLUTIONS AND RECOMMENDATIONS

In order to improve the performance of NLP applications, the types of errors have to be identified precisely enough to make an assumption for the reasons for the errors.

In Automatic Speech Recognition often only the word error rate is reported, with some distinctions in the test sets, e.g. acoustical quality or the gender of the speaker. Appropriate tools would be required to make a more precise analysis.

Such tools should be able to make a basic analysis of the types of errors (deletion, insertion, substitution). Then, a linguistic breakdown regarding the length of the words, their inflections, their part-of-speech (noun, adjective, verb ...), and other linguistic factors, might turn out to be useful. Additionally, speech rate, other prosodic factors, the level of background noise and other factors, could be included into the analysis by using the source audio signal or appropriate annotations of it.

When such a tool is available, several ASR systems might be tested and compared to make an estimate of which system performs better or worse with particular types of errors. Then, further research would be necessary to improve the performance of the ASR system with regard to particular types of errors for specific applications.

Otherwise, an error analysis tool would be usable, if it could provide an insight into the necessary steps and directions for error correction. This would enable post processing tools in which errors are further removed. It would also be useful to determine which ASR system results in recognition output with the least amount of work, if manual corrections would be applied.

The evaluation of Machine Translation output is an important and, at the same time, difficult task. A great deal of effort of the research community has been spent on finding automatic metrics which will enable ranking between different MT systems. Developed metrics correlate well with human judgments. It is useful, but to improve an MT system, additional information is needed in terms of errors that the MT system makes. This article presented an overview of the most common errors when translating a highly inflectional language. To judge a specific MT system, a systematic analysis is needed of errors in the system's output. Humans do it most commonly. The idea is to define automatic error analysis using external linguistic knowledge. It will provide more specific information of certain translation problems, on which the developer can focus and get ideas about possible improvements of the system. In (Popović & Ney, 2011) automatic error analysis has already been studied. It was based on position-independent WER in the first step to localise errors, and the application of linguistic rules in the second step to classify errors in different categories. A similar approach could be applied to highly inflected languages, as each language pair and each translation direction give rise to different translation errors.

Having the whole picture about translation errors of a specific MT system, automatic error correction methods should be investigated afterwards. It would probably be safer to apply error correction as a post-processing step. If we would try to model these aspects in translation models, changes in the model could trigger some other aspect of the translation in a negative way. Improvements in translation quality could also be expected if parallel corpora used for training MT systems had more training data.

MT systems are commonly developed for the general domain. As MT will always be error-prone, to limit the number of errors, MT can be developed as a domain-specific system. If we can detect the target domain of MT system usage, the system can be adopted for this specific domain. Consequently, the vocabulary is limited, and we avoid many mistranslated words.

Another method of improving the performance of NLP applications is their restriction or adaptation to specific domains. Domain knowledge increases the effectiveness of NLP methods. Domain specific methods reduce data sparsity and, consequently, improve the accuracy of the NLP task. The domain

of a target environment can be determined manually or detected automatically. Knowing the domain, domain-specific models are built. To train them, domain-specific data is needed. General-domain models are then adapted to a specific domain.

To build a domain-specific ASR system, a vocabulary and language model can be adapted to the target domain. The adaptation of vocabulary means that the vocabulary is extended with words specific to the target domain (for example with terminological terms). Also, words that do not occur in this domain might be excluded from the vocabulary. Using a fixed or adapted vocabulary, the language model can be adapted by training n-grams on domain-specific text. Those n-grams can define a component added to the general-domain language model.

The experiments show that general purpose translation systems usually perform poorly and, hence, it is important to develop translation systems for specific domains. The domain-specific MT is usually based on general-domain parallel corpora and domain-specific monolingual corpora. MT domain-adaptation can be data centric and model centric. Data centric methods focus on selecting training data from general-domain parallel corpora based a domain-specific language model. Model centric methods interpolate domain-specific and general-domain models in either a model level or instance level. Domain-adaptation has been studied widely for SMT, for the latest state-of-the-art NMT models it is a new and important future direction. Using domain specific dictionaries also improves MT significantly, as it solves many word sense disambiguation problems. How domain specific dictionaries could be used in NMT is also an open question. Using the unknown word replacement suffers from noisy attention.

FUTURE RESEARCH DIRECTIONS

Today, basic reserch tools for ASR and MT do not perform a thorough analysis of recognition or translation errors. Further research and development of appropriate tools would be an essential step, not only for the purpose of developing better applications, but also to understand the causes of errors and inner mechanisms of NLP applications.

Furthermore, the results of such an automatic analysis shall be used for adaptation or performacnce enhancement of NLP applications. This can also be done in conjunction with a manual error analysis. Then, those methods can also be adapted for inflectional languages by taking into account their morphological characteristics.

CONCLUSION

In this article, we presented an overview of errors that occur in NLP applications. Because natural language is a very complex phenomenon, it is not expected that in the future we could resolve all the errors occurring in NLP applications, but the number of errors could be reduced if they are analysed systematically. The article focuses on two NLP applications, that are used most widely in practice, ASR and MT. Challenges that we face in these two applications are different, although some types of errors occur in both of them. The difference between them also lies in the form in which the language is expressed. In ASR, it is a speech, and in MT it is a text. ASR copes with problems that arise in the acoustic realization of language, and MT with problems of textual realizations of natural languages. In the article, we presented the most common errors. Being aware of them is useful, because it gives ideas for further improvements of NLP methods. In the case of MT, error analysis is useful for the estimation of post-

editing effort. The question that needs a clear answer is if the effort to post-edit a sentence is expected to be lower than the effort to translate the sentence from scratch. The answer depends not only on MT errors but also on the translator's experience and skills. Nevertheless, it is an indicator of MT systems' usefulness. The article shows that there is still a lot of room for future research, which will make NLP applications even more attractive.

KEY TERMS AND DEFINITIONS

Automatic Speech Recognition: The automatic process of a machine to recognize spoken words from an audio signal or recording.

Inflectional Language: A language, where inflectional morphemes determine several morphological properties of a word.

Language Morphology: A subdiscipline of linguistics, which studies the formation of words in sentences.

Machine Translation: Translation of text or speech from the source language to the target language by a computer, with no human involvement.

Machine Translation Error: Error made by machine translation system. To some extent, machine translation errors differ from errors made by human translators.

Machine Translation Evaluation: Evaluation of translations, which resulted from Machine Translation. The evaluation can be manual or automatic. Automatic evaluation is done using an evaluation metric. The evaluation metric assigns a quality score to a translation by comparing it to the reference translation.

Natural Language Processing: A modern research area, dealing with the interaction between humans and computers with language.

Speech Recognition Error: The omission, insertion, or misrecognition of a word in the process of speech recognition.

Speech Recognition Vocabulary: The set of word a speech recognition system is able or designed to recognize.

Text-Based Image Retrieval Using Deep Learning

INTRODUCTION

This chapter is an advanced version of the previous chapter named ‘An Insight into Deep Learning Architectures’ in the book, ‘Encyclopedia of Information Science and Technology, Fourth Edition’. The earlier chapter was submitted by VIT University. It is already an established fact that information retrieval is of two types, image retrieval, and text retrieval. Image retrieval is further divided into a query and content-based approach. The main focus of the chapter will be the same as the earlier version, on Image Retrieval. In the previous edition of this book, the authors attempted to solve information retrieval problems using deep learning architectures. The authors looked on the RBMs, DBNs, and CNNs, how they can be used wisely to solve the issue of image retrieval from queries and text. This chapter will look at some of the advanced architectures (after RBMs and DBNs) used in the text-based approach.

What is information retrieval? Information retrieval means retrieving information from web or data present around us. Information retrieval is of two types image and text; information can be retrieved in either textual form or image form. Google Image search engines are an example of image retrieval. Retrieving documents from text is an example of text retrieval.

Image retrieval is done by deep learning architectures in action. Certainly, CNNs (convolutional neural nets) play an important role, they are the backbone of the image recognition tasks, with the help of NLP (natural language processing techniques) extracting the important features from the text-based query becomes an easy task. Feature learning is an important task while learning for images and text matching, this issue was resolved by using unsupervised approach DBN (Deep Belief Nets) and using new type of architecture was discovered named RBMs (Restricted Boltzmann Machines). After using simple RBMs, there has been a discovery of a new method named Multimodal Learning with Restricted Boltzmann Machines.

What is modality? In this world, information comes through various input channels. Some images have captions and tags, videos have visual and audio signals, sensory perception includes simultaneous inputs from visual, auditory, motor and haptic pathways. Each modality is characterized by separate statistical properties which makes it difficult to disregard the fact that they come from different input channels. Using the combinations of such modalities to jointly represent image and text helps in better models like for example, take an image of a car and words ‘A Car’, they are assigned a high probability to one conditioned on other. This approach is the base of Multi-modal RBMs.

In the supervised learning side, after CNNs came into existence, there have been dire need of an architecture which can remember past inputs and predict the future input and then came into existence,

DOI: 10.4018/978-1-7998-3479-3.ch007

new architecture RNNs (Recurrent Neural Nets). RNNs play an important role in textual analysis, time series forecasting, sound and speech recognition.

BACKGROUND

Recurrent neural nets belong to the class of artificial neural networks (ANNs) designed specifically to recognize patterns in the sequences of data, such as text, handwriting, speech, or numerical time-series data which can be gathered from sensors, stock markets, and government agencies. These algorithms have a major focus on time and sequence, looking towards the temporal dimension. They are considered to be one of the most powerful and useful types of a neural network, alongside the attention mechanism and memory networks. RNNs are applicable even to images, which can be decomposed into a series of patches and treated as a sequence. Traditional neural nets could not use the sense of persistence, they failed to perceive the future input because of not able to remember the sequence in which the input was fed, these neural nets have basically two inputs, first they take the input of the previous activation function of the previous input and also consider the present input and they apply activation function of the resultant to get new activation function and predict the output. This can be understood by the figure drawn below.

Figure 1.

Here, RNN is being *unrolled* (or unfolded) into a full network. The formulas that govern the computation happening during a RNN area unit as follows:

- is the input at time step . x_0 is a one-hot vector with respect to 1st word of a sentence.
- is the hidden state at time step . It's the “memory” of the network. is calculated supported the previous hidden state and also the input at this step:

$$s_t = f(Ux_t + Ws_{t-1}) \quad (1)$$

The function “f” usually is a non-linear such as tanh or ReLU (Rectified Linear Unit Function). S_{-1} , the first hidden state, is typically initialized to zero vector.

- O_t is the output at step t . In order to predict the next word in a sentence, result will be the vector of probabilities across the defined vocabulary $O_t = \text{softmax}(Vs_t)$.

RNNs started failing for longer time instances, for example,

“**Cat was** [playing with a ball of fur and] **it was** enjoying it very much.”

“**Cats were** [playing with a ball of fur and] **they were** enjoying it very much”

In the above example, there is a significant time gap between the “cat was” and “it was”. Hypothetically, RNNs are completely fit for taking care of such “long term dependencies.” A human could cautiously pick parameters for them to take care of toy issues of this structure. Tragically, in practice, RNNs don’t seem to be able to learn them. The main problem is of Vanishing Gradient. In Vanishing gradient problem, when dealing with activation functions like the sigmoid function,

$$S(x) = \frac{1}{1 + e^{-x}} = \frac{e^x}{e^x + 1} \quad (2)$$

Lies in [0,1] and when all the numbers between [0,1] are multiplied, the resultant gets smaller and smaller. So, the little estimations of function’s subsidiaries (happening in the mistake work) gets increased on different occasions as the user moves towards the beginning layers. Subsequently, the slope nearly vanishes as he moves towards the starting layers, and it winds up hard preparing these layers. This problem was resolved by a newer net called Long Short Term Memory nets which evolved with the idea of retaining the longer time gaps information so that they can be relayed successfully.

$$i = \sigma(x_t U^i + s_{t-1} W^i) \quad (3.1)$$

$$f = \sigma(x_t U^f + s_{t-1} W^f) \quad (3.2)$$

$$o = \sigma(x_t U^o + s_{t-1} W^o) \quad (3.3)$$

$$g = \tanh(x_t U^g + s_{t-1} W^g) \quad (3.4)$$

$$c_t = c_{t-1} \bullet f + g \bullet i \quad (3.5)$$

$$s_t = \tanh(c_t) \bullet o \quad (3.6)$$

LSTM is merely an another way to compute hidden state, just as equation (i) was used to compute in RNN. Now, looking at the above equations:

1. Here, i, f, o are the input, forget and output *gates*, respectively, they all have similar equations as in (i) but with different parameters. These equations are called *gates* because they use sigmoid function as an activation to squeeze the values of the vectors in the range of 0 to 1, and using the elementwise product with another vector they can be used to define the ratio of dominance of the other vector in the result. Following gates define the following:
 - A. Input gate defines the ratio of the newly computed state for the current input.
 - B. Forget gate defines the ratio of the previous state.
 - C. Finally, output gate defines the ratio of the internal state that is needed to expose to the external network.

All the gates have the same dimensions d_s , the size of the hidden state.

2. g is a “candidate” hidden state that is computed based on the current input and the previous hidden state.
3. c_t is the internal memory of the black box. It is the resultant of the previous memory c_{t-1} multiplied with forget gate, and the newly computed candidate state g , multiplied with input gate.
4. Using c_t , computing the output of hidden state s_t by multiplying the memory with the output gate. This gating mechanism was used to solve the problem of vanishing gradient.

MAIN FOCUS OF THE ARTICLE

Multimodal Deep Boltzmann Machine

Deep learning architectures like RBMs (Restricted Boltzmann Machines) have been used earlier in text based image retrieval, new type of architecture called Multimodal-DBM uses a twin type architecture to solve the problem. RBMs were originally developed for modelling binary vectors but **Gaussian-Bernoulli RBMs** are used in modelling pixel intensities and filter responses.

Energy function:

$$E(v, h; \theta) = \sum_{i=1}^D \frac{(v_i - b_i)^2}{2\sigma_i^2} - \sum_{i=1}^D \sum_{j=1}^F \frac{v_i}{\sigma_i} W_{ij} h_j - \sum_{j=1}^F a_j h_j \quad (4.1)$$

Distribution Function:

$$P(v; \theta) = \frac{1}{Z(\theta)} \sum_h \exp(-E(v, h; \theta)), Z(\theta) = \int_v \sum_h \exp(-E(v, h; \theta)) dv \quad (4.2)$$

And **softmax replication model** is used in word count vector representation. This model is a type of Restricted Boltzmann Machine in which the binary variables, have been replaced by multinomial one of a number of different states. Energy Function:

$$E(V, h) = -\sum_{i=1}^M \sum_{j=1}^F \sum_{k=1}^K W_{ijk} v_{ik} h_j - \sum_{i=1}^M \sum_{k=1}^K b_{ik} v_{ik} - \sum_{j=1}^F a_j h_j \quad (5.1)$$

Probability Function:

$$P(V, h; \theta) = \frac{1}{Z(\theta)} \exp(-E(V, h; \theta)), Z(\theta) = \sum_V \sum_h \exp(-E(V, h; \theta)) \quad (5.2)$$

A **Deep Boltzmann Machine** is a network of symmetrically coupled binary units and it contains the set of visible and hidden 3 layered DBM:

$$E(v, h; \theta) = -\sum_{i=1}^D \sum_{j=1}^{F_1} W_{ij}^{(1)} v_i h_j^{(1)} - \sum_{j=1}^{F_1} \sum_{l=1}^{F_2} W_{jl}^{(2)} h_j^{(1)} h_l^{(2)} - \sum_{l=1}^{F_2} \sum_{p=1}^{F_3} W_{lp}^{(3)} h_l^{(2)} h_p^{(3)} \\ - \sum_{i=1}^D b_i v_i - \sum_{j=1}^{F_1} b_j^{(1)} h_j^{(1)} - \sum_{l=1}^{F_2} b_l^{(2)} h_l^{(2)} - \sum_{p=1}^{F_3} b_p^{(3)} h_p^{(3)} \quad (6)$$

And so when we use **Multimodal DBM**, it is far more advanced version of the current RBM and uses the below architecture infused with Softmax Replication and Gaussian-Bernoulli RBM.

Figure 2. Image Specific: Gaussian-Bernoulli RBM and Text Specific: Softmax Replication RBM and joining both of them Multimodal DBM

Multimodal RBM belongs to the family of unsupervised artificial neural network. Probability function of the above figure can be given as:

$$\begin{aligned}
 P(v^m, v^t; \theta) &= \sum_{h^{(2m)}, h^{(2t)}, h^{(3)}} P(h^{(2m)}, h^{(2t)}, h^{(3)}) \left(\sum_{h^{(1m)}} P(v_m, h^{(1m)} | h^{(2m)}) \right) \left(\sum_{h^{(1t)}} P(v^t, h^{(1t)} | h^{(2t)}) \right) \\
 &= \frac{1}{Z_M(\theta)} \sum_h \exp \left(\underbrace{\sum_{kj} W_{kj}^{(1t)} v_k^t h_j^{(1t)} + \sum_{jl} W_{jl}^{(2t)} h_j^{(1t)} h_l^{(2t)} + \sum_k b_k^t v_k^t + M \sum_j b_j^{(1t)} h_j^{(1t)} + \sum_l b_l^{(2t)} h_l^{(2t)}}_{\text{Re plicated_softmax_text_pathway}} \right. \\
 &\quad \left. - \sum_i \frac{(v_i^m - b_i^m)^2}{2\sigma_i^2} + \sum_{ij} \frac{v_i^m}{\sigma_i} W_{ij}^{(1m)} h_j^{(1m)} + \sum_{jl} W_{jl}^{(2m)} h_j^{(1m)} h_l^{(2m)} + \sum_j b_j^{(1m)} h_j^{(1m)} + \sum_l b_l^{(2m)} h_l^{(2m)} \right. \\
 &\quad \left. + \underbrace{\sum_{lp} W_{lp}^{(3t)} h_l^{(2t)} h_p^{(3)} + \sum_{lp} W_{lp}^{(3m)} h_l^{(2m)} h_p^{(3)} + \sum_p b_p^{(3)} h_p^{(3)}}_{\text{Joint_3rd_Layer}} \right)
 \end{aligned} \tag{7}$$

But DBMs started failing because, the model started showing lesser relevance measure than the supervised models and this model lacked scalability. Model size increased rapidly thereby increasing the error. Recurrent Neural Nets proved to be efficient in word vector transformation.

Recurrent Neural Nets (RNN)

Due to their capability for processing arbitrary-length sequences, recurrent neural nets are a natural choice of sequence modelling tasks. Recurrent neural nets create count vectorizer and pair the words, so that they can be used get the desired image. They create vector representations and using the previous knowledge of RNNs as discussed in previous section, they map it to the CNN (convolutional neural net) for image mapping. Earlier state-of-art techniques were used to create word representations like making use of concepts like tf-idf vectorizer, count vectorizer, lemmatizer, bag of words. But now this all work is done using RNN.

CT-RNN (Constituency Tree RNN)

Constituency Tree Recurrent Neural Net proves to be more efficient than the existing RNN architecture, certain function is used to compute the sentence representation, it's not like the simple RNN which averages the overall vector and maps the image based on that. CT-RNN use the binary tree data structures. They have the child-parent principle. These constituency tree RNNs (CT-RNNs) use the following composition function to compute a hidden parent vector 'h' from exactly two child vectors (c_1, c_2) in a binary tree:

$$h = f(W \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}) \tag{8}$$

where $W \in \mathbb{R}^{d \times 2d}$ is the main parameter to learn.

Figure 3.

DT-RNN (Dependency Tree RNN)

Sentence vectors of previous models cannot accurately represent visually grounded meaning. This led to the discovery of the DT-RNN model which uses dependency trees to embed sentences into a vector space in order to retrieve images that are described by those sentences. In this model, the network learns to map sentences (based on RNNs) and images into a common embedding space in order to be able to retrieve one from the other. Word and image representations are first learnt in their respective single modalities and then finally mapped into a jointly learned multimodal embedding space.

But learning word representations is not simply based on RNNs or CT-RNNs, there is a new architecture called Dependency Tree- RNN. The DT-RNN can solve the following problem:

The mother hugged her child.

The child was hugged by its mother.

Both the above sentences should map to roughly the same visual space but present recursive and recurrent neural networks do not exhibit this behavior and even bag of words representations would be influenced by the words 'was' and 'by'. The example, $\text{Students}_{(x1)} \text{ride}_{(x2)} \text{bikes}_{(x3)} \text{at}_{(x4)} \text{night}_{(x5)}$ computes sentence representation in bottom up fashion.

Figure 4.

In a bottom up fashion, the DT-RNN model computes parent vectors at each word that include all the dependent (children) nodes using a compositionality function g_θ which is parameterized by all the model parameters θ .

$$h_c = g_\theta(x_c) = f(W_v x_c) \quad (9)$$

Assume $l(i)$ be the number of leaf nodes (words) under node i and $C(i, y)$ be the set of child nodes of node i in dependency tree y . The final composition function for a node vector h_i becomes

$$h_i = f\left(\frac{1}{l(i)}(W_v x_i + \sum_{j \in C(i)} l(j) W_{pos(i,j)} h_j)\right) \quad (10)$$

where by definition $l(i) = 1 + \sum_{j \in C(i)} l(j)$ and $pos(i, j)$ is the relative position of child j with respect to node i . Further to add-on, semantic DT-RNN (SDT-RNN) is similar to the above equation except that the matrices $W_{pos(i,j)}$ are replaced with matrices based on the dependency relationship.

Long Short Term Memory (LSTM)

LSTMs have been discussed in the previous section, they emerge as an effective and representational power at capturing long term dependencies. There are different variations of LSTM, like:

Bidirectional LSTM, it consists of two LSTMs that are run in parallel: one on the input sequence and the other on the reverse of the input sequence. At each time step, the hidden state of the Bidirectional LSTM is the concatenation of the forward and backward hidden states. This setup allows the hidden state to capture both past and future information.

Multilayer LSTM, in the architecture, the hidden state of an LSTM unit in layer l is used as input to the LSTM unit in layer $l+1$ in the same time step. Here, the idea is to let the higher layers capture longer term dependencies of the input sequence.

Constituency Tree LSTM and Dependency Tree LSTM use the same above described functions to create word representations. Dependency Tree LSTMs prove to be most effective in compared to all the architectures discussed till now.

Dependency Tree structures prove to be useful and so few changes made in them and they create a whole new set of deep architectures. In an extensive research held by the authors, it is concluded that segmentation and fragmenting of images and word sentences have increased the accuracy in spite of the old architectures.

Attention Mechanism in LSTM-trees

Despite the fact that LSTMs take care of the RNN's vanishing gradient issue, they are constrained to linear data. LSTM these days' use tree-structured organization to experience the issue of dominant input words. On the off chance that basic LSTMs were utilized, at that point the last piece of the sentence gets more significance with respect to the starting part. But, if the tree structure of the sentence gets traversed from base to top then the data from various constituents initially gets combined to represent the root at the upper level and afterward this roots step by step gets traversed as children and joined to represent the root

at next dimension, etc. So in the two cases a LSTM cell will overlook past data which for plain LSTM, is identified with the length of the sentence and for Tree-LSTM, is identified with the depth of the tree.

When viewing the tree as a semantic representation of a sentence, this may not be the situation in numerous situations. For a constituency tree, if a sub-tree contains some negative sentiment words, at that point it isn't always the case that the constituent is negative. If the negative sentiment word is preceded by an invalidation (i.e. not bad, not ugly), at that point the constituent turns out to be semantically positive due to the nullification word (not). To catch this sort of data, attention is applied over the sub-tree parts to distribute the significance of each sub-tree segment when building the whole tree either semantically or linguistically. In the recent discovery, semantic attention is applied over the sub-tree components. Some attention weights are given to the children of the sub-tree and then the resultant is computed based on the weights.

SOLUTIONS AND RECOMMENDATIONS

Previous attempts to encode the word embeddings in LSTMs were only successful for smaller paragraphs and attention mechanism as discussed in the LSTM-tree architecture can be applied to all of the above. Multimodal and agent based learning as used in Deep Boltzmann Machines can be used similarly in other deep learning architectures as well. Mapping of image into vector space is also a crucial task as sentences with similar meanings might not end up in the same visual space which creates the room for error, these mistakes can be avoided by properly regulating the architectures using error functions and hyperparameter tuning. Certain type of generative network has come into existence which generates new data based on the previous data, and nowadays images don't come with tags, so this algorithm might come in handy.

FUTURE RESEARCH DIRECTIONS

Vectorized representation of the word sentences plays an important role in text based image retrieval. As discussed in the previous section there is an open window for using GANs (general adversarial networks) in order to overcome the problem of tagging which images in this era face and using attention mechanism on GANs may improve the performance, text based retrieval is a never ending field, some variations on the input side and functions involved will lead to the creation of new architecture. Further advancements have been made using image as the search query and also combining both (image and text as query) has proven to be quite successful. Some of the famous search engines also use image based information retrieval and the result comes out to be more promising than the past researches.

CONCLUSION

Deep learning has been proven to be a boon to the field of information retrieval and deep learning architectures have experienced a major breakthrough going from simple CNNs then to DBNs and then to RBMs as discussed in the previous version of the book. The chapter was concentrated only to the text based image retrieval but in the field of information retrieval itself there are different types which remain untouched. This article pours deep into the future of the chapter called, "An Insight to Deep

Architectures”, published in the encyclopedia. The innovative methodology of using RNNs in text based query processing which revolutionized NLP. This article also focused on the depth of the meaning of the sentence, how each and every word links with each other in order to get more accurate image results.

KEY TERMS AND DEFINITIONS

Convolutional Neural Networks: A multi-layer neural network similar to artificial neural networks only differs in its architecture and mainly built to recognize visual patterns from image pixels.

Deep Boltzmann Machine: A deep Boltzmann machine (DBM) is a type of binary pairwise Markov random field (undirected probabilistic graphical model) with multiple layers of hidden random variables.

General Adversarial Network: General adversarial network (GAN) is a deep learning, unsupervised machine learning technique. It has a generator and a discriminator. Generator generates the new data and discriminator discriminates between generated input and the existing input so that to rectify the output.

Image Retrieval: An image retrieval system is a computer system for browsing, searching and retrieving images from a large database of digital images. Most common utilized methods are adding metadata to captioning, keywords etc.

Long Short-Term Memory: Long short-term memory (LSTM) is an artificial recurrent neural network (RNN) architecture used in the field of deep learning. The cell remembers values over arbitrary time intervals and the three gates regulate the flow of information into and out of the cell.

Recurrent Neural Networks: A recurrent neural network (RNN) is a class of artificial neural networks where connections between nodes form a directed graph along a temporal sequence. This allows it to exhibit temporal dynamic behavior.

Dynamic Load Balancing Using Honey Bee Algorithm: Load Balancing

INTRODUCTION

Distributed system include a set of interconnected and virtual computers that are provisioning dynamically. The Distributed system and cloud computing characteristics are basically as on-demand access, broad network access, resource pooling, rapid elasticity, measured service and security.

Providing the virtualization technology in cloud platforms helps enterprises to rent computing power in the form of virtual machines to the users. The users may utilize hundreds or thousands of Virtual Machines (VMs). To handle a very large size of data many techniques to optimize load and simplify operations are needed to obtain desirable performance level for the users. There is a need an effective algorithm in term of load balancing in the cloud computing. The load can be differentiated in various categories, CPU load, delay or network load, memory capacity. Load balancing guarantee that each processor in the system does approximately the same quantity of load at any point of time. The task scheduling is used to determine the suitable resources to execute the tasks that received from users. For increasing the utilization of resources, we use the load balancing algorithm. Efficient utilization is achieved by using the idle resources until finishing the resources of processors that have the high load. The load balancing mechanism divides the loads within all the resources which are available. The dynamic cloud computing used many of load balancing strategies. The Max-Min algorithm for each task, the minimum completion time is calculated, then the task with the maximum of minimum completion time is mapped to the corresponding virtual machine. The Shortest Job-First (SJF) is a various algorithm to CPU scheduling. This way associated with every process length's next CPU burst. The process with shortest length assigned to CPU when it is available. When there are two processes that have same CPU bursts then scheduling based on FCFS. In Round Robin (RR) approach, the processes are separated between all processor. Every process is mapping the processor in a round robin order by using quantum time. The allocation of process is not based on the allocations from remote processors. The processing time of task for various processes is not equal but the distributions of workload are same.

DOI: 10.4018/978-1-7998-3479-3.ch008

With the ever increasing size of the systems, there is a greater need for load balancing. The servers tend to get over worked and are rendered useless in catering to the needs of millions of users, and hence deny the services. So, a challenge in this modern era of smart computing is to make use of the various Load Balancing techniques to get the servers to function efficiently. Various algorithms are used for balancing the overall load of the cloud and a few of them are the honey bee foraging algorithm, a biased random sampling on a random walk procedure and Active clustering. Here, we will focus on the honeybee foraging algorithm and write a pseudo code for it, as well as develop a generic system model. The honeybee foraging algorithm is inspired from the behavior of honeybees for finding and reaping food. There is a type of bees called the forager bees who continually search for food sources and upon finding the same they return to the hive and advertise their discovery by a dance called as the waggle. The type of the movements in the dance reveal the quality and quantity of the food source as well as the distance of it from the beehive. Scout bees follow the forager bees to the location and reap the food. In case of load balancing in the web servers, whenever the demand sees a spike there is a dynamic allocation of services to regulate the changing demands of the user. The servers are grouped under Virtual servers (VS), each virtual server is assigned a specific queue for itself. Each server while processing a request calculates the reward and this is analogous to the quality of the find. The dance floor in case of the bees can be analogous to the advert board here which advertises the reward to the entire colony. Each server takes the role of either a forager or a scout. If the profit is high then the server stays at the current virtual server; posting an advertisement for its profitability (pr), if it was low then the server returns to the forage or scout behavior.

As mentioned earliest, the users send the requests to the service provider, the service provider has to serve many users to provide the best results and take into account maximizing resources utilization. Distributing the tasks into the resources to avoid overloading where there are under loaded resources. The objectives of this work to achieve users' satisfaction and provider satisfaction by balancing the loads and increase resources utilization, by minimizing the average of both make span time and response time using LBDA algorithm effective performance.

Proposed honey bee behavior inspired load balancing (HBB-LB) to achieve a good balance load through VMs for maximizing the throughput. We have compared the results of our proposed algorithm with the currently used algorithms. The results prove that our proposed algorithm has yielded better and efficient scheduling.

BACKGROUND

In an appropriated framework, dynamic load adjusting should be possible in two distinctive ways: distributed and non-distributed. In the conveyed one, the dynamic load adjusting calculation is executed by all hubs display in the framework and the errand of load adjusting is shared among them. The collaboration among hubs to accomplish stack adjusting can take two structures: cooperative and non-cooperative. Karaboga, D., & Ozturk, C. (2011)

In the first, the hubs work one next to the other to accomplish a typical target, for instance, to enhance the general reaction time, and so on. In the second frame, every hub works freely toward an objective neighborhood to it, for instance, to enhance the reaction time of a nearby local task. Dynamic load adjusting calculations of conveyed nature, normally create a larger number of messages than the non-dispersed ones on the grounds that, each of the hubs in the framework needs to connect with each other hub. An advantage, of this is regardless of the possibility that at least one hubs in the framework come

up short, it won't bring about the aggregate load adjusting procedure to stop, it's rather would impact the framework execution to some degree. Appropriated dynamic load adjusting can present massive weight on a framework in which every hub needs to trade status data with each other hub in the framework. It is more invaluable when a large portion of the hubs demonstration separately with not very many communications with others. Banerjee, S et al., (2009).

In non-distributed sort, it is possible that one hub or a gathering of hubs do the undertaking of load adjusting. Non-distributed dynamic load adjusting calculations can take two structures: centralized and semi-distributed. In the principal shape, the heap adjusting calculation is executed just by a solitary hub in the entire framework: the focal hub. This hub is exclusively in charge of load adjusting of the entire framework. Alternate hubs cooperate just with the focal hub. In semi-distributed frame, hubs of the framework are divided into bunches, where the heap adjusting in each group is of concentrated shape. George, G., & Raimond, K. (2013).

A focal hub is chosen in each group by suitable race procedure which deals with load adjusting inside that bunch. Subsequently, the heap adjusting of the entire framework is done by means of the focal hubs of each bunch.

Centralized dynamic load balancing takes less messages to achieve a choice, as the quantity of general associations in the framework diminishes radically when contrasted with the semi-distributed case. In any case, brought together calculations can bring about a bottleneck in the framework at the focal hub and furthermore the load balancing procedure is rendered pointless once the focal hub crashes. Accordingly, this calculation is most suited for systems with smaller size.

FOCUS OF THE ARTICLE

The enhanced artificial honey bee colony calculation (ABC), an advancement calculation in light of the savvy searching conduct of honey bee swarm was proposed by Karaboga, D., & Ozturk, C. (2011)

This metaheuristic is roused by the keen scrounging conduct of bumble bee swarm. The calculation exhibited in the work is for numerical function advancement. The advantage of ABC is that the global search ability in the algorithm is implemented by introducing neighbourhood source production mechanism Rastkhadiv, F., & Zamanifar, K. (2016).

In the ABC calculation, the honey bees in a settlement are partitioned into three gatherings: employed honey bees (forager honey bees), onlooker honey bees (observer honey bees) and scouts (explorer honey bees). The principal half of the settlement comprises of the employed honey bees and the second half incorporates the onlooker bees.

The employed honey bee whose nourishment source has been depleted by the honey bees turns into a scout for looking new sustenance sources haphazardly. An employed honey bee conveys the data about nourishment source and imparts this data to a specific likelihood by waggle move. Then again onlooker bees watch the waggle move as are put on the nourishment sources by utilizing a probability based choice process. As the nectar measure of a sustenance source builds, the probability with which the nourishment source is favored by onlooker bees increments, as well Tang, K., Zhang, J. M et al.,(2011).

Bees can learn the directions and distances of their travels between hive and food sources by a process called path integration. A natural nourishment source is indicated in the honey bee's memory by a vector encoding distance and direction from the hive. This vector that is the yield of the way path integration process is employed for route on ensuing trips to the nourishment, and it is additionally what the honey

bee encodes in its waggle move. Some honey bee state based calculations have been planned with motivation from honey bee's navigational framework.

Calculations that take their motivation from the honey bee's home site choice conduct apply the guideline of choice making process that empowers a settlement to distinguish and unite towards one best arrangement Padhy, R. P., & Rao, P. (2011).

SOLUTIONS AND RECOMMENDATIONS

Figure 1. System Architecture

A users send a request about required resources, task priority and task size request to cloud manager in the bee colony optimization. The cloud Manager Store all requests. Now if forms a request table with required resources, task priority and task size request from all users. Then apply bee-Colony algorithm for all entry and Schedule and Assigns the channel according to Bee-Colony algorithms output Fitness value.

Honey Bee Behavior Inspired Load Balancing

1. Initialize a population of n scout bees.
2. Evaluate the fitness of the population.
3. Select the m sites for neighborhood search.
4. Recruit bees for selected sites.
5. Select the best fitness bees from each patch
6. Assign task to VM
7. Calculate load balance.
8. Stop the procedure

We implemented the Artificial Bee Colony Optimization algorithm to the numeric problem.

FUTURE RESEARCH DIRECTIONS

There are various other aspects that could not be taken into consideration while researching for this work and can be further bettered and presented in future works.

CONCLUSION

Hence, upon observing a plethora of test cases, we can safely find the best case. Hence, there must be a ratio of number of different kinds of bees for us to reach at a better solution. Thus, we have shown three of the test cases out of the various that we have executed to show the general trend of the graphs upon changing the various test conditions.

KEY TERMS AND DEFINITIONS

Artificial Honeybee Colony Calculation (ABC): It is a swarm based meta-heuristic algorithm that was introduced by Karaboga in 2005 for optimizing numerical problems.

Dynamic Load Balancing: Assignment of tasks to a computational platform, with the objective of balancing the work assigned to processors. When the tasks are interdependent an additional objective is to minimize communication between processors. The load balance is monitored during execution of the application, and the assignment is modified if required, while trying to minimize the communication cost of migrating tasks.

Honeybee Algorithm: The bees algorithm is a method of problem solving that mimics the behavior of honeybees to find the optimum solution.

Virtual Servers: A virtual server is a server that shares hardware and software resources with other operating systems (OS) versus dedicated servers.

Waggle Dance: A wagging movement performed by a honeybee at the hive or nest, to indicate to other bees the direction and distance of a source of food.

Unsupervised Automatic Keyphrases Extraction on Italian Datasets

1

Isabella Gagliardi

INTRODUCTION

Keyphrase extraction is an important research activity in text mining, natural language processing, and information retrieval. Keyphrases provide a compact semantic representation of the content of a document. Many tools for text management that automate tasks requiring high skill and expertise can benefit from the keyword extraction process (Zhang, 2008). To obtain the keywords, the texts should be analyzed to extract terms that characterize or represent the content of the documents and are useful in identifying documents relevant to a given query and/or in “suggesting” something in some way related. Keyphrases should represent the content of a document in all its aspects and be general enough to represent more than a single item, as well as specific not to represent the whole set of items. Keyphrases should, therefore, satisfy the following characteristics: i) have good coverage; ii) be relevant; iii) be consistent and iv) be up-to-date.

This process can be performed manually (associated or identified by experts, for example museum curators, in the case of Cultural Heritage) or automatically. The manual association of keywords to documents requires time, skills, specialized staff, and more steps to ensure that the chosen terms are consistent, adequate, relevant, with a good coverage, sufficiently general and timely. A large number of algorithms, divided into supervised or unsupervised methods, have been designed and developed to solve the problem of automatic keyphrases extraction. Supervised methods typically consider this problem as a classification task, in which a model is trained on annotated data to determine whether a given phrase is a keyphrase or not. Supervised approaches and systems can be found in Turney, 2000; Hulth, 2003; Hulth & Megyesi, 2006; Zhang, 2006; Nguyen & Kan, 2007; Hong & Zhen, 2012. These systems require a great number of training data, which can be unrealistic in the web scenario, and yet show a bias towards the domain on which they are trained. Keyphrase extraction task in unsupervised approaches is considered as a ranking problem. Unsupervised means that no human supervision is required: the algorithms are able to identify autonomously, and without any prior training, the terms to be extracted.

The aim of the chapter is to critically discuss the Unsupervised Automatic Keyphrases Extraction algorithms, analyzing in depth their characteristics. The methods presented will be tested on different datasets, presenting in detail the data, the algorithms and the different options tested in the executions. Moreover, most of the studies and experiments have been conducted on texts in English, while there are few experiments concerning other languages, such as Italian. Particular attention will be paid to the evaluation of the results of the methods in two different languages, English and Italian.

The chapter is organized as follows: after the description of the state-of-the-art of unsupervised keyword extraction methods, the algorithms, the data, the pre-processing methods applied, and the

DOI: 10.4018/978-1-7998-3479-3.ch009

experimental runs are presented. The results obtained are then presented, compared and evaluated, and future research discussed.

BACKGROUND

To identify the most relevant keywords for a text, the following pipeline has to be performed, that mimics the Information Retrieval one:

- Pre-process data
- Apply Unsupervised Automatic Keyword Extraction Algorithms:
- Extract a list of candidate keywords /keyphrases using some heuristics,
- Score each candidate keywords/keyphrases, according to different criteria and methods,
- Select the first m keywords/keyphrases.
- Evaluate the results.

Each step will be described in detail below.

Pre-Processing

Pre-processing (Kannan & Gurusamy, 2014; Vijayarani, Ilamathi, & Nithya, 2015, Uysal, & Gunal, 2014) has the aim of preparing the texts for the algorithms of keyword extractions. In this chapter datasets in English and Italian languages are considered. The steps in both languages are the same, but the methods, tools, experiences available for the two languages are different. English-language datasets can rely on well-established pre-processing tools and methods capable of eliminating, if useful, stoplist words and terms belonging to defined grammatical categories. Tokenization, lemmatization/stemming, POS (part-of-speech) tagging tools, and almost standard stopword lists can be easily identified and applied to obtain acceptable results.

The situation for the Italian language is more nuanced: the Italian grammar, morphology, and syntax are more complicated. As an example, some part of speech, as nouns and adjectives, are variable, that is, they are modified according to the number (singular and plural) and gender (feminine and masculine). The adjective beautiful, for the positive grade, takes shapes ‘*bello*’ (masculine/singular), ‘*bella*’ (feminine/singular), ‘*belli*’ (masculine/plural), and ‘*belle*’ (feminine/plural).

For each piece of text, the following steps, rather standard, will be taken, not necessarily in this order:

1. **tokenization**, that is, division of the text into individual single/multi words;
2. annotation, that may include **POS tagging**;
3. **normalization**: lemmatization/stemming;
4. removal of the **stopwords** and/or specific grammatical categories.

Tokenization is the process of decomposing a text, considered as a continuous set of words – or a string-, into a set of terms, composed of a single or compound words. This apparently trivial process is language dependent, as the characters that indicate the end of the word are different from language to language. In Italian, for example, the apostrophe is a character of division of words. It is obligatory in case of elision, such as a *bell'amico* (good friend) or *quest'alunna* (this (girl) student). In these cases, two

distinct words should be identified. In English the use of the apostrophe is different, e.g. for the Saxon genitive, or in case of contraction or abbreviation, not giving rise to two different words.

Moreover, regardless of language, different methods can be applied to identify compound words. For example, you can use statistical methods that identify groups of words frequently together and consider them as n-gram, or use headlines of Wikipedia page as a dictionary or identify their presence in WordNet.

POS (part-of-speech) tagging is the process of associating the corresponding grammatical category to every single word. Table 1 shows possible grammatical categories, taken from “Italian tagset used in the TreeTagger¹”.

Table 1. Italian tagset used in the TreeTagger parameter file

VER:cpre verb conjunctive present
...

This process requires understanding the structure of the sentence because, in Italian as in English, the same word can belong to different grammatical categories (e.g. be an adjective, a noun or a verb) depending on the composition of the sentence. For example in Italian, ‘*danza*’ (dance) in ‘*lui danza*’ (he dances) is a verb, while ‘*la danza*’ (the dance) is a noun.

Normalization: the process of lemmatization/stemming reduces the words to the lemma or stem. The two processes are different. The Porter algorithm is the most widespread stemmer for the English language. For example, according to the Porter stemmer (Porter, 1980) or Snowball algorithm (Porter, 2001), ceremony, as ceremonies, become *ceremoni*. The lemmatizes, on the other hand, should bring the various inflected forms to a single lemma, that is, the voice present in the vocabulary. For example ceremony, ceremonies should lead to ceremony; or listening, (he) listens, (they) listened, ... to “to listen”. For Italian, there are no similar “universal” algorithms.

Stopword: traditionally, in information retrieval systems, texts to be indexed are provided without stopwords, those words that are so frequent that they have no meaning: for example and, in, is/are, Obviously, stoplists are different for Italian and English. Also, depending on the context of use, they

should be customized. There are various lists of generic stopwords, both for Italian and English. For example, in Ranks NL website² there are several stoplists for English, while only one for Italian³.

The results of the pre-processing are lists of headwords or vocabularies, to be used - together with the original data - for the next steps of text analysis.

Algorithms

Although the problem of extracting keyphrases able to represent the content of pieces of text in natural language has been faced since the first Information Retrieval systems appeared, the advent of new tools and techniques makes it still very actual: in literature, many papers are devoted to this topic (Hasan & Ng, 2010; Hasan & Ng, 2014; Merrouni, Frikh, & Ouhbi, 2016; Siddiqi & Sharan, 2015) and several approaches have been defined (Gollapalli, Caragea, Li, & Giles, 2015; Hulth, 2003; Mihalcea & Tarau, 2004; Rose, Engel, Cramer, & Cowley, 2010).

Keyphrase extraction task in unsupervised approaches can be gathered into statistical-based, graph-based and cluster-based approaches. In statistical-based approaches, texts are usually represented as matrices in which the statistical techniques are applied to rank the words by using Tf-idf term weighting metric (Manning, Raghavan, & Schütze, 2010). In graph-based methods each document is represented as a graph where vertices or nodes represent words, and edges are connected based on either lexical or semantic relations, such as a co-occurrence relation. Examples are TextRank (Mihalcea et al., 2004), RAKE (Rose et al., 2010), SingleRank or CollabRank (Wan & Xiao, 2008a, 2008b). Cluster-based methods extract terms, group them into clusters based on their semantic relatedness using Wikipedia and/or other co-occurrence similarity measures, and select phrases that contain one or more cluster centroids. Examples are KeyCluster (Liu, Li, Zheng, & Sun, 2009) or SemCluster (Alrehamy & Walker, 2017).

In the following, the methods used in these experiments are presented, that is *Tf-idf*, *TextRank*, *RAKE*. Besides the results obtained applying *Latent Semantic Indexing* and *Latent Dirichlet Allocation*, able to extract topics from texts, are also described and discussed.

Tf-idf

Tf-idf is the short form for *term frequency–inverse document frequency*, widely used in Information Retrieval (Salton & Buckley, 1988; Manning et al., 2010) to measure the importance of a word in a document, within a collection or corpus. The Tf-idf weight is composed by two terms: normalized Term Frequency (TF), and the Inverse Document Frequency (IDF), and computed as follows:

TF: Term Frequency measures how frequently a term occurs in a document. For normalization purpose, the term frequency is divided by the document length:

$$TF(td) = \frac{\text{Number of times term } t \text{ appears in document } d}{\text{Total number of terms in document } d}$$

IDF: Inverse Document Frequency measures how important a term is. Frequent terms are weighed down, while scaled up the rare ones, by computing the following:

$$IDF(t) = \log_e \frac{\text{Total number of documents}}{\text{Number of documents containing term } t}$$

Tf-idf assigns to a term a weight in a document that is: a) highest when the term occurs many times within a small number of documents (thus lending high discriminating power to those documents); b) lower when the term occurs fewer times in a document, or occurs in many documents (thus offering a less pronounced relevance signal); and c) lowest when the term occurs in almost all documents.

Tf-idf has been used extensively in information retrieval systems, and in general in search engines because i) is easy to compute, ii) cosine ranking formula sorts documents by degree of similarity to the query. On the other hand, being based on the bag-of-words (BoW) model, it does not capture the position in the text, semantics, co-occurrences in different documents.

TextRank

TextRank is a graph-based ranking model for text processing (Mihalcea et al., 2004), is based on the same assumptions of Google's PageRank (Brin & Page, 2012; Page, Brin, Motwani, & Winograd, 1999), that is: i) important pages are linked by important pages, and ii) the PageRank value of a page is essentially based on the probability that a user visits that page.

TextRank models a text document as a graph where each word (or sentence, according to granularity chosen) in the document is represented as a node, and the semantic relation between each node is represented by an edge. A scoring algorithm will then be executed on the graph to assess the value of each word, which will be used to rank them, then top ranking words are selected as keywords. Keywords that are adjacent in the document are combined to form multi-word keywords.

Main characteristics of TextRank are: it

- finds keywords that appear “central” (like PageRank);
- can be applied to any text without prior training;
- is domain independent;
- works on each single document;
- can generate keyphrases.

RAKE

RAKE, short form for Rapid Automatic Keyword Extraction (Rose et al., 2010) is an unsupervised, domain-independent, and language-independent method for extracting keywords from individual documents. It is graph-based.

The algorithm is composed of the following steps: i) it extracts a set of candidate keywords (single words or sequences of contiguous words), ii) assigns a score to these candidate keywords, based on the co-occurrence graph: the score is based on the frequency of the words and their degree (the sum of lengths of all sequences where the word appears), iii) adjoins keywords and iv) extracts the top ranking keywords.

Main characteristics of RAKE are: it

- can be applied to any text without prior training;
- is domain independent;
- works on each single document;
- can generate more complicated phrases;
- needs a comprehensive and reliable list of stop words.

Latent Semantic Indexing (LSI)

The idea behind LSI is to compare words to find relevant documents, but what you really want is to compare the meanings or concepts of words. LSI (Dumais, 2004; Landauer, 2006) is a technique able to analyze relationships between a set of documents and the terms they contain by producing a set of concepts related to the documents and terms.

LSI assumes that words that are close in meaning will occur in similar pieces of text. A term-document matrix, like that created by Tf-idf model, is the starting point for the technique - called Singular Value Decomposition (SVD) - used to reduce the number of rows in the matrix, while preserving the similarity structure among columns, thus converting terms and documents to points in a lower-dimension space.

Steps to apply LSI to a set of documents:

- Create the word by document matrix. In this matrix, each index word is a row and each document is a column;
- Apply *Tf-idf* weighting to the matrix;
- Apply upon the matrix the SVD technique to obtain a reduced dimensional representation of matrix that emphasizes the strongest relationships and throws away the noise.
- Words are then compared by taking the cosine between the two vectors formed by any two rows. Values close to 1 represent very similar words while values close to 0 represent very dissimilar words.

LSI is able to cluster documents into n topics, n defined ahead, assigning each topic to a set of words. The belonging of a document to a cluster is scored with a numeric value $[0,1]$. Depending on the number of documents and the homogeneity/variety within each document and between documents (intra and inter-document), the number of clusters can be difficult to define.

Latent Dirichlet Allocation (LDA)

LDA is a technique that automatically detects topics contained in documents (Blei, Ng, & Jordan, 2003). The steps to identify topics, words and to associate documents with topics are:

- define the number of topics: it can be done either using an informed estimate (for example the results of a previous analysis), simply by trial and error or based on the best Coherence and perplexity values calculated on different numbers of topics;
- the algorithm will assign each word to a temporary topic, semi-randomly. This means that if a word appears twice, this word can be assigned to different topics;
- (iterative) the algorithm will check and update topic assignments, looping through the words of each document. For each word, the topic assignment is updated according to two criteria: 1) How common is this word across topics? and 2) How prevalent are topics in the document?

The process of checking topic assignment is repeated for each word in every document, cycling through the entire collection of documents multiple times. This iterative updating is the key feature of the LDA to generate a final solution with coherent topics.

Both LSI and LDA are algorithms for topic modelling, and the result is a set of n topics, n defined ahead, each containing a set of scored words or phrases. According to the different implementations,

the number of words/phrase for each topic can be defined. Both the words/phrases assignment to topics and documents assignment to topics are scored. The choice of the number n of topics can be difficult, and methods other than trial and error can be implemented.

Evaluation

Designing evaluation metrics for automatic unsupervised keyphrase extraction algorithms is by no means an easy task. In general, the results are compared with the keywords chosen manually by experts or using gold standard datasets.

According to SemEval contexts⁴, in this chapter Recall and Precision, borrowed by Information Retrieval, will be used to assess the results.

Recall measures the ability of the system to retrieve *all* relevant items in the corpus and can be expressed as (see Table 2):

$$\text{Recall} = \frac{\text{Number of relevant documents retrieved}}{\text{total number of relevant documents}}$$

Or, expressed according to confusion matrix (Table 3):

$$\text{Recall} = \frac{\text{True positive}}{\text{True Positive} + \text{False Negative}}$$

In other words, *recall* is the fraction of relevant documents that have been retrieved over the total amount of relevant documents and its value is 1 when all the relevant instances are retrieved, decreasing up to 0 when none relevant instance is retrieved.

Precision measures the ability of a search engine to retrieve *only* relevant items in the corpus and can be expressed as:

$$\text{Precision} = \frac{\text{Number of relevant documents retrieved}}{\text{total number of retrieved documents}}$$

Or

$$\text{Precision} = \frac{\text{True positive}}{\text{True Positive} + \text{False Positive}}$$

Table 2. Classical Information Retrieval matrix

	Retrieved	not retrieved
Relevant	Retrieved & relevant	Retrieved & relevant
Not Relevant	Retrieved & not relevant	Not retrieved & not relevant

Table 3. Confusion Matrix

		Predicted	
		Negative	Positive
Actual	Negative	True Negative	False Positive
	Positive	False Negative	True Positive

Precision is the fraction of relevant documents among the retrieved documents, and its value varies from 1 to 0, with 1 if only relevant documents are returned, and 0 if none relevant document is retrieved. Sometimes it is used $P@n$, precision measured on the first n topmost results returned.

Figure 1 shows an example of computation of values of Recall, Precision and $P@n$. In an ideal system, both recall and precision should tend both to 1; in a real world system, depending on the user's needs, recall or precision tend to be favored: recall when there are few important documents to retrieve, precision when the dataset is wide, and the loss of some documents is less important than the retrieval of many useless documents.

Figure 1. Example of Recall and Precision computation

n	doc n.	relevant	
1	675	x	
2	690	x	
3	576		
4	590	x	
5	986		
6	592	x	
7	984		
8	988		
9	578		
10	985		
11	103		
12	591		
13	772	x	
14	990		

Let total number of relevant documents = 6

Recall = $1/6=0.167$; Precision = $1/1=1$

Recall = $2/6=0.333$; Precision = $2/2=1$

Recall = $3/6=0.5$; Precision = $3/4=0.75$

Recall = $4/6=0.667$; Precision = $4/6=0.667$

Recall = $5/6=0.83$; Precision = $5/13=0.38$

Missing one relevant document.
Never reach 100% recall

THE EXPERIMENTATION

In the following the experiment test bed will be described, starting from the datasets, the pre-processing methods applied, concluding with the algorithms and their evaluation, showing some results obtained.

Datasets

To test the algorithms 6 different datasets, in Italian and English languages, have been used, as described below:

CookIT

1

CookIT portal⁵ stores multimedia information describing, in Italian language, the traditional recipes handed down from generation to generation. The choice of the recipes to be inserted has been made by interviewing people of different ages, social conditions, and Italian regions to identify the recipes they consider as part of their own tradition and culture. Recipes are collected from the most relevant traditional recipes websites in Italy, such as Cucina Italiana⁶, Giallo Zafferano⁷. At the moment, 140 recipes have been added to the portal, and about 450 traditional Italian recipes have been identified and are being edited.

Lombardy Digital Archive: AESS (Archivio di Etnografia e Storia Sociale)

The AESS database (Artese & Gagliardi, 2012) stores information related to the oral history of the Lombardy region. The documents (interviews, songs, transcription of texts, transcription of music, scores, manuscripts, sound files, images, photographic documents, videos) are the result of targeted ethnographic and anthropological field research. They are an impressive and continuously updated corpus of traditional intangible culture in the Lombardy territories. Currently, the archive consists of 15,000 oral documents, among them about 4500 records related to photographs, in Italian language, have been used for the experimentation.

Intangible Search (Italian)

This is an online collection of “living good” of Lombardy Region and Alp territories, created from Lombardy Digital Archive (Artese & Gagliardi, 2013). IntangibleSearch⁸ offers information in several languages: Italian, English, French and German⁹, being the result of a cross-border EU project, ECHI, involving partners from all over the Alpine region: Italians, Swiss, French. 254 Italian-language documents, available on the web, have been used here.

Intangible Search (English)

This is the English subset of the IntangibleSearch, described above. About 166 English-language documents have been used.

Europeana

Europeana¹⁰ is the European platform for digital cultural heritage, built as a result of several EU-funded projects (Haslhofer & Isaac, 2011). More than 3,000 European institutions have contributed to building this vast collection, allowing users to explore Europe’s cultural and scientific heritage from prehistory to the present day. A set of metadata, in all European languages, is collected and integrated into a single collection, while data is stored in the original location, without any duplication. For this experiment, metadata has been extracted, through some queries, considering only those in English, for a total of 1928 documents.

Victoria and Albert Museum

The V&A museum¹¹ is the world's leading art and design museum, with a vast collection of over 2.3 million objects covering over 5,000 years of human creativity. The collections cover the theater, art books, painting, glass, ceramic architecture, furniture, fashion, textiles, photography, sculpture, jewelry, Asian art and design. Detailed information and descriptions have been extracted for this experiment, together with tags (if available), for a total of 558 documents.

Table 5 summarizes the main information on the 6 datasets used, three in Italian and three in English. If present, tags associated by catalogers or experts have been used in the tests.

Table 5. information on the 6 datasets used

	Cookit	AESS	Intangible	Intangible	Europeana	V&A

Average Words no.	288	35	454	465	58	248
Tags no.	47	4588	263	165	682	539

With the aim of testing the algorithms, and identifying if (and, if so, which) method produces better results on this data with a set of test queries, and if there is any difference between English and Italian, a standard Information Retrieval approach was followed.

Pre-Processing

For the datasets in English and Italian, the pre-processing phases are the same, while the specific tools and algorithms to be applied differ. For the English language, data sets were processed using standard tools, such as Stanford's core NLP suite¹², Natural Language Toolkit of Python (Loper & Bird, 2004), or the NLTK package with PENN Treebank as a POS tagger and tokenizer (Marcus, Marcinkiewicz, & Santorini, 1993). Initially, the same tools were also used for Italian - where they were present - but the results obtained were not useful due to the presence of too many errors and inaccuracies, both for the POS tagging and for the lemmatization. Subsequently, tools developed specifically for the Italian language were tested, for example, the Italian version of Snowball¹³, Pattern python package specific for Italian (Pattern clips 2.6) or Lingua (Dell'Orletta, 2009; Attardi, Dell'Orletta, Simi, & Turian, 2009). In the end, TreeTagger (Schmid, 1994) was chosen, a free tool developed by Helmut Schmid in the TC project at the Institute for Computational Linguistics of the University of Stuttgart, using the Italian standard tagset. A second tagset was also tested, but the results were not as satisfactory.

We applied different pre-processing methods to the datasets:

Table 6. The 10 top most frequent terms for the 2 datasets, according to the different pre-processing methods applied

The top 10 Most Frequent terms					
Dataset\pre-processing method	orig_nouns	orig_nouns_adj	tokens	tokens_nouns	tokens_nouns_adj
Cookit	minuto acqua olio impasto salalsale fuoco pasta forno farina modo	minuto acqua olio impasto salalsale fuoco pasta forno farina piatto	il minuto poi aggiungere fare acqua cuocere lasciare circa olio	acqua olio fuoco impasto pasta sala farina forno modo ciotola	minuto acqua olio fuoco impasto pasta sala forno farina piatto

Original data: no pre-processing steps applied (orig)

Tokens: only tokenization of texts (tokens)

Tokens more than 1: only tokens appearing more than once are kept (tokens_moreonce)

After POS tagging, tokens that are nouns (`_nouns`), and tokens that are nouns and adjectives (`_nouns_adj`) were held on the three processed datasets (orig, tokens, tokens_moreonce).

The 10 Most frequent and the 10 Least frequent terms are shown in Table 5 and Table 6 for 2 datasets (one data set in Italian and one in English) according to the different pre-processing methods applied. You can see that the different pre-processing methods select a set of different terms, thus leading to very different keywords/keyphrases extracted by the algorithms.¹⁴

Algorithms

The following Unsupervised Keyphrases Extraction algorithms, described in section 2, have been tested and evaluated:

- Tf-idf
- TextRank
- RAKE
- Latent Semantic Indexing
- Latent Dirichlet Allocation.

Tf-idf was tested using 1-gram basis for word extraction: in Artese & Gagliardi, 2018 results are reported for n-gram tests; for TextRank only nouns and adjectives have been selected as potential keywords; for LSI, tests were performed with a different number of topics: here are reported the results for 20 and 100 topics, for LDA perplexity values and coherence were evaluated to identify the best number of topics.

Some algorithms have to be performed document by document (TextRank, RAKE), while others must be executed on the whole collection of documents (Tf-idf, LSI, LDA).

According to the Information Retrieval diagram, automatically extracted keyphrases are then used for document indexing in a spatial vector model and cosine similarity is the metric chosen to retrieve and rank documents in response to the request. Each execution on an algorithm/dataset/pre-processing method gives rise to a different set of keywords (weighted), associated with each document: so that the list of retrieved documents can be different both in the documents and in the retrieval order. Table 7 shows information and some statistics on the results obtained, applying the 5 algorithms on Italian Cookit pre-processed dataset. For other datasets/pre-processing methods, similar values have been obtained. In this phase, the same parameters were applied to the pre-processed datasets, having modified, as described, stopword lists, POS tagging, and stemming algorithms.

Evaluation

The implemented algorithms were tested on the (pre-processed) datasets, using the queries of which those in Table 8 are a subset. The results were assessed in terms of recall and precision.

TextRank and RAKE index each document only with top ranked terms and when a query is executed, the matching algorithm retrieves and scores only those documents that have terms in common with the query, the other documents are not retrieved. On the other hand tf-idf and (to some extent) LSI and LDA

Table 8. Some information and statistics on the results obtained on the Cookit dataset

Algorithm/ Dataset	Pre-processing method	Average text length	Average number of keyphrases per doc	No. different keyphrases	Average length of keyphrases	No. keyphrases with more than 10 occurrences

Table 9. Example of queries used to test the algorithms

Cookit	AESS	Intangible-IT	Intangible-EN	Europeana	V&A
impasto zucchero forno mozzarella mandorla spada acciuga	piadena anno impianto fotografia cascina festa lavoro	pietra processione latte chiesa statua carnevale paese	statue mask puppet procession carnival church people	silk lace plate needle cake credit brussels	miniature oil portrait ivory simple glass watercolour

algorithms give a weight to each term in the document: thus, in essence, documents are sorted according to the weight of the terms in the query.

For this reason, the precision of TextRank and RAKE is always very high and around 1, thus confirming the high quality of the algorithm results. On the other hand, recall values can be low because only those documents to which the searched terms have been associated are retrieved.

Tf-idf, LSI and LDA order the results according to the cosine similarity values of the vector space. Tf-idf obtains precision@10 and P@20 value almost close to 1, with lower precision on 100 items. LSI and LDA have high value of recall, at the expenses of precision. The results of LSI vary as the number of records varies. For example, on AESS, which contains more than 4000 documents, the results of LSI 20 show that very different elements are grouped together in the same topic. So we can conclude that 20 clusters are too few. LDA algorithm uses coherence and perplexity values give hints on the optimal number of topics.

For example, Victoria & Albert museum dataset has been evaluated on ‘cheese’ query. The dataset contains 84 items to be retrieved.

With *Tokens* pre-processing, Tf-idf retrieves 74 items, RAKE 0, TextRank 14, LSI-100 302 and LDA 120 with a number of topics of 35. For Tf-idf precision value is 1, and recall is 0,88, for RAKE 0, while TextRank has precision 1 and recall 0,18, LSI-100 has recall 1,00 and precision 0,24, and LDA 35 has recall 0,89 and precision 0,61.

With *Orig* pre-processing Tf-idf retrieves 73 items, RAKE 8, TextRank 9, LSI-100 319 and LDA-35 139. For Tf-idf precision value is 1, and recall is 0,86, for RAKE 0, while TextRank has precision 1 and recall 0,18, LSI-100 has recall 1,00 and precision 0,24 and LDA-35 has recall 0,96 and precision 0,57.

On another query, ‘portrait’, the same dataset contains 270 items to be retrieved.

With *Tokens* pre-processing, Tf-idf retrieves 273 items (of which relevant 263), RAKE 2, TextRank 49 (of which relevant 41), LSI-100 404, and LDA-35 342. For Tf-idf precision value is 0,96, and recall is 0,97, for RAKE almost 0, while TextRank has precision 0,83 and recall 0,15, LSI-100 has recall 1,00 and precision 0,66. LDA-35 has recall 0,99 and precision 0,77.

With *Orig* pre-processing Tf-idf retrieves 264 items, RAKE 50, TextRank 41, LSI-100 406, and LDA-35 345. For Tf-idf precision value is 1, and recall is 0,86, for RAKE 0, while TextRank has precision 0,83 and recall 0,15, LSI-100 has recall 1,00 and precision 0,66. LDA-35 has recall 0,99 and precision 0,76.

The experimental setup has been implemented in Python 2.7, using standard packages like Numpy, Matplotlib, Pandas and other more specific ones for processing of textual data such as NLTK (Loper & Bird, 2004), Gensim (Řehůřek & Sojka, 2011), Newspaper¹⁵, Pattern (Pattern clips 2.6), and Sklearn¹⁶ together with some experimental packages in GitHub.

SOLUTIONS AND RECOMMENDATIONS

The algorithms for automatic unsupervised extraction of keywords/keyphrases are a topic of great scientific interest, given the large availability of texts on the web. The experiments described have shown that by changing methods, tools and applying different parameter values to the algorithms, the results can also vary greatly.

It is worth noting that:

- Tf-idf, TextRank and RAKE algorithms produce scored keywords, while LSI and LDA produce n topics composed of unscored keywords.
- RAKE obtains results only on the original texts, without the lemmatization and elimination of stopwords;
- the number of different keyphrases varies greatly on the basis of the algorithm tested and pre-processing applied: from 67 of LSI with 20 topics to over 2000 of tf-idf, excluding RAKE;
- TextRank produces a relatively large number of keywords, using the recommended values: setting a threshold value, as the maximum number of keywords extracted per document or the weight of the nodes must be further tested and evaluated;
- TextRank, RAKE extract keyphrases longer than 1.
- LSI basically works as a clustering algorithm, associating each cluster with a set of keywords that represent it. The results reported were obtained by choosing 20 and 100 as the number of topics.
- LDA too works as a clustering algorithm: to identify the optimal number of topics, per each dataset/pre-processing method, coherence and perplexity have been evaluated. For Cookit dataset the optimal number of topics is 25.

The analysis of these results shows that the algorithms behave in the same way on datasets in English and Italian. What would require further analysis is the Italian-language pre-processing. For example in pos tagging/lemming, all the systems tested show errors or inaccuracies in both processes, especially with verbs in the presence of combined pronouns, resulting in a faulty recognition.

FUTURE RESEARCH DIRECTIONS

Tests have shown that further work could lead to optimized results and should be geared towards:

- Identify and test other pre-processing tools, specifically designed for the Italian language for better POS tagging and lemmatization results;
- implement and test other algorithms and methods, such as Keycluster, SingleRank, ExpandRank, or deep learning methods;
- integrate different algorithms (results) to obtain the best keywords;
- integrate word2vec, GloVe, WordNet or Babelnet to manage synonyms and identify topics in a more efficient and effective way;
- extend the experimentation to other languages, such as French, German or Spanish;
- test algorithms on other media files and/or on larger data sets;

- further study evaluation tasks, both testing different ways to create a set of keywords for comparison/evaluation, and investigating other methods, borrowed also from information retrieval or image tagging.

CONCLUSION

The aims of these experiments have been to test and evaluate different automatic unsupervised keyword/keyphrase extraction algorithms; and evaluate if there are differences in processing Italian vs English datasets.

Five algorithms present in literature have been tested on six different datasets and the results of the experimentation have been reported here, to evaluate which algorithm works best, in terms of recall and precision, with respect to query tests. The experiments described have shown that by changing methods, tools and applying different parameter values to the algorithms, the results can also vary greatly.

The results on Italian vs English datasets, evaluated in terms of recall and precision, are mainly influenced by pre-processing methods and specific tools, rather than by algorithms.

KEY TERMS AND DEFINITIONS

Automatic Keyword Extraction Algorithms: Algorithms able to extract keywords from texts, automatically and in an unsupervised manner. They are usually based on probability, graph, or on clusters.

Bag of Documents Model: Is a representation of a text as a set of its words, holding multiplicity (how many times each word appears), but losing position and other related information.

Dataset: Is a collection of data. Usually referred to a coherent set of data, such as records of a single database, or even of a single table.

Keywords/Keyphrases: Single or compound words able to characterize the content of the documents, useful for identifying the documents relevant to a given query.

Information Retrieval: Is the activity of searching information, relevant to user's needs from a collection of documents. Documents usually are texts, but can be images, video, or sounds.

Lemmatization: Is the process of reducing inflected forms of a word to its dictionary form or lemma.

POS (Part of Speech) Tagging: Is the process of assigning to each word of a text a particular part-of-speech, as verb, nouns, adjective, adverb, and so on. Different languages need different POS tagging tools.

Stemming: Is the process of reducing inflected forms of a word to its root or stem.

INTRODUCTION

Information is an imperative concept that humans use to communicate because communicating aids understanding. Within an information, there could be other components of data such as images, video, numbers and text. The need to stay informed in modern day has resulted in various ways of transmitting information with the use of technologies such as the computer and internet. Hence, Information and Communication Technologies (ICT) has played an important role in this aspect. ICT is the use of modern equipment and methods to transmit and exchange information. ICT has helped in understanding the human society and way of life. The applications of ICT include research and development in a variety of application fields such as teaching, transport, business, entertainment, politics, agriculture, medicine and various industry and academic disciplines among others. One of such disciplines, that this article is based on, is archaeology.

Archaeology is a discipline that recovers, studies and analyses ancient and modern artefacts and material remains from past societies of humans and closely related species, recording its primary data for the purpose of reusing them for historical understanding of human culture (Jeffrey, 2010:47). Archaeologists have used ICT as a means of making, keeping and preserving records and information to make it available for further research and future use (Eiteljorg, 2004; Marchetti *et al.*, 2017; A. Smith, 2004). This is to considerably reduce the likelihood of information degradation and loss (A. Smith, 2004). Hence, various methods have been used by social scientists and digital humanists to preserve historical artefacts and relics such as literary texts and arts, frescoes and potsherds (Sabharwal, 2015:60-61).

In particular, archaeologists have employed different time-consuming means of studying and preserving historical relics (Marchetti *et al.*, 2017). Such methods include physical examination, classification, illustration and reconstruction of potsherds through drawing. These methods are carried out manually, making the archaeologist spend time and effort to observe and possibly extrapolate from the observations (Drucker, 2012:89). However, reconstruction of many excavated fragments of potsherds is still a major concern. This paper proposes a path towards an optimal means to reconstruct excavated archaeological potsherds to a high standard. To achieve this, image analysis techniques (computer vision) as well as machine learning algorithms are considered.

In addition, the terms ‘reconstruct’ and ‘reassemble’ are used interchangeably in this paper to mean the same thing. The remainder of this paper is structured as follows: Section 2 reviews some related works from a general point of view and highlights the potentials inherent in computer vision and ma-

DOI: 10.4018/978-1-7998-3479-3.ch010

chine learning; Section 3 delves into the research problem, identifying the research questions, methods, objectives and methodology that this study is based on; Section 4 concludes our discussion.

BACKGROUND

As archaeologists study the historic and prehistoric human activities through reconstructing discovered ancient artefacts to have a grounded understanding of the prehistoric culture, the ability to carry out these reconstructions accurately and within reasonable time become pertinent. In this technology era of virtual and augmented reality, among others, researchers have been applying the use of digital technologies to make work faster and output optimal. This has helped in making professional life easier, more enjoyable and more productive, leading to what is now known as ‘smart environment’. Therefore, applying technological means to solve critical issues in the archaeological field is desirable.

Hence, many studies have attempted to solve the reconstruction problem. For example, the study of Kampel and Sablatnig (2003) developed a system that can process both complete and broken vessels. This was achieved using two reconstruction strategies known as: “shape from silhouette based method for complete vessels and a profile based method for fragments” (Kampel & Sablatnig, 2003). While using these strategies have improved performance with an acceptable accuracy, it is nonetheless dependent on certain conditions being met, thus requiring further investigations that will improve accuracy.

Likewise, Smith, Bespalov, Shokoufandeh and Jeppson (2010) investigated methods of classification and reconstruction of images of excavated archaeological ceramic fragments based on their colour and texture information. This was achieved by using Scale Invariant Feature Transform (SIFT) and a feature descriptor based on Total Variation Geometry (TVG) (P. Smith *et al.*, 2010). However, the performance of these descriptors was not satisfactory in terms of effectiveness and accuracy. Also, the study of Puglisi, Stanco, Barone and Mazzoleni (2015) proposed a system that uses SIFT as well. The system uses image processing techniques to automatically identify and analyse images of the structural components of potsherds through “optical microscopy”. As a result, the suitable features can then be computed and analysed for classification purposes. In addition, this system aims at segmenting the acquired images and extracting their features for pottery classification. To achieve this and for the sake of better accuracy, the authors chose to use SIFT feature point method, where the feature points are extracted and matched with related pairs. While this system improves on the ones before it, it falls short in providing an optimal solution with a high accuracy, hence opening the path to further studies (Puglisi *et al.*, 2015).

Furthermore, Makridis and Daras (2012) focused on a technique for accurate and automatic classification of potsherds. The technique was implemented in four steps namely: feature extraction, feature fusion, feature selection and classification. This approach attempted to reduce the computational complexity problem with a “bag of words (BoW)” method that uses the features extracted from the images to create a “global descriptor” vector for the images (Makridis & Daras, 2012). However, while this technique turned out to be quite efficient, how and if this solution reduces computational complexity is still an open issue.

Finally, Roman-Rangel, Jimenez-Badillo and Marchand-Maillet (2016) proposed Histogram of Spherical Orientations (HoSO), a method for automatic analysis of potsherds by applying computer vision techniques. This method analyses the external frontal view of the potsherd alone, processes 3D data by using only the points coordinates without using colour, texture or faces, and efficiently encodes the information from the points coordinates. They posit that the advantages include substantial time reduc-

tion in potsherd organisation and a simple method of acquiring the image (Roman-Rangel *et al.*, 2016). This shows that advantages are inherent in the application of computer vision techniques.

Potentials of Computer Vision and Machine Learning in Pottery

Among various modern digital techniques that are becoming relevant for archaeological studies, both computer vision and machine learning are emerging. Vision is the ability to use the brain to sense and interpret the surrounding environment with light reflected by objects in the environment. This is demonstrated when archaeologists apply the manual method of potsherds reassembly. On the other hand, computer vision is the science of building systems that make useful decisions to obtain information from digital images or complex image data (Forsyth & Ponce, 2012). In other words, the ability to make machines to see and do what the human perception can. Computer vision can perform feature detection, extraction, fusion and selection, then analyse it to understand the information perceived from images or imagery data (Forsyth & Ponce, 2012). Other potentials of computer vision include reconstruction, tracking, recognition, restoration and learning. In addition, a computer vision system that is well designed will increase productivity.

Image Acquisition and Processing

In any image processing project, the image acquisition stage is the first. Without this stage, there is no project that can be done. The image is first acquired by an optical device such as a camera and processed into a manageable form. According to Moeslund (2012), “the image acquisition process consists of three steps namely: energy reflected from the object of interest, an optical system which focuses the energy and finally a sensor which measures the amount of energy”. Also, various methods exist for acquiring the image depending on the project to be done. After the image has been acquired, processing and enhancements can be carried out. However, the image acquisition will need to be done in a satisfactory manner for the processing to be satisfactorily done.

While the image can be acquired in 2D and converted into 3D, it can also be directly acquired in 3D. In the studies of Díaz-Marín *et al.* (2015), Stamatopoulos and Anagnostopoulos (2016) and Tsiafaki, Koutsoudis, Arnaoutoglou and Michailidou (2016), image acquisition was effected in 3D. However, the methods of acquisition differ from one to the other. Where Díaz-Marín *et al.* and Tsiafaki *et al.* used a laser scanner and a camera to acquire images in 3D, Stamatopoulos and Anagnostopoulos acquired images in 2D by panoramic photography with a digital camera, which were then transformed into 3D with a “specialised software”.

Although image acquisition in 3D has many advantages over acquisition in 2D, its use and prevalence in cultural heritage requires more investigation. While 2D images give a limited information of the physical shape and size of an object, 3D images express the geometry in terms of three-dimensional coordinates. Furthermore, current technological advancement in camera and laser technologies have made the production of an optimal and accurate 3D depth data achievable. Hence, numerous 3D data acquisition systems have been developed. These systems can be applied in cultural heritage studies, and archaeology in particular, as is the case in this study.

Machine and Deep Learning

Machines are capable of learning and processing information around them, a process that can be referred to as pattern recognition and learning techniques. These techniques are usually categorised as artificial intelligence or machine learning. For example, supervised learning is a machine learning technique. While computer vision techniques have been extensively exploited in the attempt to automate pottery reconstruction, as cited above, no serious effort has been devoted to the application of new techniques based on machine learning.

Machine learning allows machines to accurately predict outcomes for the future by learning about the past without the machine being explicitly programmed (Haykin, 2009; Marsland, 2015). Machine learning algorithms are categorised into supervised learning and unsupervised learning. In supervised learning, both the input and the desired output are provided with supervision so that the machine can learn and apply the knowledge to new dataset (Alpaydm, 2010; Haykin, 2009). In unsupervised learning, only input data is provided unsupervised while the machine iteratively computes and arrives at its deduction. Machine learning has helped in proffering solutions to problems in various disciplines. While prominent results of application of these techniques include: self-driving cars, speech recognition, face recognition, biometric recognition, spam mails detection, effective web searches, applications in computer vision, robotics and medical diagnosis, and a host of other improvements (Alpaydm, 2010; Marsland, 2015), optimal performance could be obtained when these methods and techniques are applied to classification and reassembly problems. With these potentials in view, cultural heritage disciplines and archaeology in particular can benefit from these technologies. Hence, the considerations of computer vision and machine learning in the application of this study.

POTSHERD REASSEMBLY: A CASE STUDY

As an example of how image analysis techniques as well as machine learning algorithms could be useful in the archaeological context, how these techniques could be put to good use in the specific field of potsherds reassembly is here presented. This should be considered as a paradigmatic and advanced case application of ICT in archaeology, since documentation and reassembly of excavated potsherds is still one of the most pressing concerns in a typical field project (Marchetti *et al.*, 2017).

Of all the artefacts recovered from archaeological excavations, pottery is one of the most significant because of its ability not to decay when compared with other archaeological artefacts of other materials (Barclay *et al.*, 2016). Depending on how the pottery is preserved, it could be recovered as a complete pot on site or as fragments known as potsherds. Most potsherds, especially the ones of the pottery rim, usually carry information such as the shape of the pottery, decoration on the pottery and colour of the pottery among others, on the inner and/or outer surfaces (Di Angelo, Di Stefano, & Pane, 2017). This information helps the archaeologist to carry out studies such as dating, and to understand the culture of the potter. However, to be able to carry out a meaningful study, there is a need to reassemble these potsherds as much as possible for a more comprehensive understanding of what is being studied. Thus, the reconstruction problem is recognised as of primary importance. Figure 1 shows some excavated archaeological potsherds.

Furthermore, reconstruction is usually done manually by attempting to physically arrange and join the potsherds together just like in a puzzle. Going a step further, reconstruction can also be done by drawing the pottery form by extrapolation from the arranged or classified potsherds (Collett, 2012) as shown in

Figure 1. Sherds of excavated Archaeological Pottery (Source: Creative Commons¹)

Figure 2; a drawing of the sectional and external views of a modern pottery vase. They represent the first step of conventional drawing by pencil on paper through comb, other technical tools and its subsequent inking, which is then effected by drawing digitally on a raster image of the pencil drawing.

However, when certain basic tasks are not taken into consideration in the reconstruction process, there is the tendency to spend a long time trying to solve the puzzle of reconstruction and not achieving it, leading to a lack of understanding and missing valuable information (Barclay *et al.*, 2016). Thus,

Figure 2. A hand-drawn and Adobe Illustrator drawing of a modern pottery vase with the left side showing the section view and the right side showing the external view

requiring better ways of approaching this challenge.

PROBLEM STATEMENT

Excavated fragments of archaeological pottery have been quite challenging to reconstruct into desired artefacts (Colantoni & Gottarelli, 2008; Makridis & Daras, 2012). According to Colantoni and Gottarelli (2008), such challenge was observed in the process of classification and study of excavated potsherds, reconstruction of potsherds by physical assembly and reconstruction of potsherds by drawing. In addition,

potsherds recovered from archaeological sites are rarely complete enough to provide useful information, hence archaeologists fall back on the time-consuming method of reconstructive drawing by extrapolation (Di Angelo *et al.*, 2017; Drucker, 2012:89). Reconstructing potsherds is significant in the field of pottery and archaeological studies, analysis and research. Barclay *et al.* (2016) note that the excavated potsherds are used as a reliable tool for dating, and as evidence for ancient tradition, culture, civilization and technology. In fact, the use of technology and computer aided techniques have impacted positively on the studies on pottery and archaeology (Collett, 2012).

However, potsherds reconstruction coupled with the time, effort and cost expended, make an optimal means of reconstruction vital. According to Barclay *et al.*, “If the study of pottery is to reach its full potential, it is vital that it is recovered and analysed to a high standard.” Hence, being able to assemble and reconstruct potsherds optimally and with ease will greatly impact pottery and archaeological studies. Unfortunately, there is little evidence that various research works have addressed this persisting issue satisfactorily with respect to a high standard reconstruction of pottery (Marchetti *et al.*, 2017; Rice, 1987:286).

RESEARCH DESIGN AND METHODOLOGY

While computer-based attempts have been made to optimally reconstruct archaeological potsherds, a viable and optimal means of reconstruction is still desired. Hence the persisting gap for investigating the reconstruction of archaeological potsherds based on the contribution that new digital technologies, such as machine learning, can provide. Consequently, to address the gap, the following research questions in Table 1 are to be researched and responded to, with partial progress made on research questions one and two.

Research Approach

Images of the potsherds are first processed by an expert archaeologist, then processed digitally. The processed images are then acquired as training data for a semi-supervised learning-based machine. The system should then be able to infer thereafter and generate an output (pottery form) from the acquired data. From an epistemological viewpoint, such an approach falls under the realist and positivist approach,

Table 1. Research Problem, Research Questions and Corresponding Research Methods and Objectives

Research problem	Excavated fragments of archaeological potsherds are quite challenging to reconstruct to a high standard at present with current approaches, leading to unnecessary time consumption.	
Research Questions	Research Method(s)	Objectives
Why is it so difficult to digitally reconstruct archaeological potsherds?	Literature Analysis	To identify the challenges and drawbacks of techniques and methods in potsherd reconstruction.
How can archaeological potsherds be reconstructed to yield a high standard form for archaeological research purposes?	Literature Analysis and Experiment	Identify and determine best processes, techniques or technologies to use in implementing an optimal solution.
How should certain technologies be applied in the reconstruction process to enable a successful form assembly?	Literature Analysis and Experiment	Identify ways to implement a viable system, and develop a framework that would make potsherd reconstruction feasible.

where experiential methods and techniques of empirical enquiry prevail over abstract interpretations. On a more practical side, the objective of this methodology is to enhance and improve the accuracy of data capture and processing, leading to an optimal potsherd reconstruction through the experiential manipulation of the technical attributes or variables employed, while reducing time consumption and efforts expended by archaeologists. All this considered and due to the nature of this problem, the quantitative methodology of research, data collection and data analysis could be adopted. Hence the following strategy should be pursued as simply described in Figure 3.

Research Design and Method

Due to the nature of this study, data would be collected and analysed using computer vision techniques and a combination of machine learning and deep learning models. Particularly, image mosaicing methods will be employed. Because of the high accuracy of deep learning models, it will be considered for feature

Figure 3. Research Conceptual Model

learning and extraction. On the other hand, machine learning will be considered for classifying the data. Following the stages discussed in Ghosh and Kaabouch (2016), this experiment has been divided into the stages in Figure 3.

1. **Registration:** This refers to the establishment of geometric correspondence between a pair of images depicting the same scene. Registering a set of images entails an estimation of the geometric transformations that align the images with respect to a reference image within that set. The set may consist of two or more images taken of a single scene at different times, from different viewpoints, and/or by different sensors.
 - **Image acquisition:** While images of the potsherds that will be used as test data will be acquired in 2D and 3D, the 3D data will be considered in this study. A different set of labelled images of potsherds, and possibly textual and painted cultural heritage fragments will be acquired and archived as training data.
 - **Feature learning:** Here features of colours, edges, corners and anything that can represent the image will be extracted to facilitate pattern detection, recognition and classification – useful for prediction and identification. This will be done using deep neural network such as Convolutional Neural Network (CNN).
 - **Classification:** Classification is performed using the features obtained from learning. Appropriate classifiers will be used in MATLAB to identify the one that gives the best result. This will be done to determine shape characteristics, segmentation and other features required to differentiate between a class of potsherds from another class.

2. Reprojection: This refers to the alignment of the images into a common coordinate system using the computed geometric transformations. Appropriate methods are applied to find borders and regions that match.
3. Stitching: At this stage, geometric description will be determined, and fragments retrieved and matched. Stitching overlays the aligned images on a larger canvas by merging pixel values of the overlapping portions and retaining pixels where no overlap occurs. Errors propagated via geometric and photometric misalignments often result in undesirable object discontinuities and seam visibility around the boundary between two images.
4. Blending: The stitched images are cropped and seamlessly blended. Blending algorithm is used during or after the stitching step to minimize the discontinuities in the global appearance of the mosaic or assembled object.

FUTURE RESEARCH DIRECTIONS

Individuating an automatic machine learning approach to pottery reconstruction can be considered of interest to archaeologists, as they could then focus on other aspects of their studies, thereby increasing productivity. With the research questions one and two already partially explored, focus will thereafter be on the third research question as well. The anticipated outcome is a system that can optimally acquire potsherds digitally and reconstruct a pottery form with the available data. Where the data is not complete, i.e. some potsherds missing, the system should be able to extrapolate from available data to complete the reassembly of the pottery. While the solution is the goal, formulating a satisfactory process is also of great importance to this study. To this end, a framework able to make image processing a less complicated task needs to be explored, while the data collected from this activity will open further opportunities in this study.

CONCLUSION

This paper presents an approach towards reconstructing excavated archaeological potsherds to a high standard and with high accuracy. This approach involves the use and application of computer vision techniques and machine learning algorithms. This will support archaeologists in the reconstructing of cultural heritage fragments as they carry out their studies. Some existing works, and the techniques and algorithms applied in them, have been discussed taking note of the impact of these techniques with respect to a high accuracy result, and their limitations. In addition, the potentials of computer vision and machine learning were highlighted by presenting existing works that have applied these techniques, noting the areas where they fall short. This led to the presentation of the potsherd reconstruction case study that this paper is based on. Furthermore, the problem statement of the study was presented, and the approach and method discussed. While the research approach falls under the realist and positivist approach, its application in a social and cultural heritage context is also significant. Hence, the objective of this methodology is to enhance and improve the accuracy of data capture and processing, leading to an accurate and optimal potsherd reconstruction. Finally, the future research directions of this study were presented with the goal of developing a framework that can make image processing a less complicated task within a pottery reconstruction context and, in general, cultural heritage as well.

KEY TERMS AND DEFINITIONS

Computer Vision: The ability to make computers or machines to see, interpret, and do similar tasks that humans can do.

Cultural Heritage: An expression of the way of life of a people, inherited and passed on from generation to generation and preserved in the present for posterity. The way of life of a people include its customs, traditions, values, knowledge, belief, law, art, and anything that is acquired and passed on.

Image Acquisition: The process of capturing an unprocessed image from an object or scene by an optical device into a manageable form for processing and analysis purposes.

Machine Learning: The science of getting computers to learn and improve their learning over time in an accurate and automatic manner, by giving them data and information.

Potsherd: A broken piece of pottery, or earthenware generally, with archaeological value.

Pottery: Vessels made from soft clay and hardened by heat.

Pottery Classification: A procedure or process of systematic sorting and grouping together of pottery or potsherd of high similarities and characteristics.

Pottery Documentation: The process of acquiring, classifying, processing, and recording pottery objects, physically or digitally, for preservation and research purposes.

Pottery Reassembly/Reconstruction: The act of restoring potsherds, physically, or digitally, so that it looks as its original condition as much as possible.

INTRODUCTION

Rapid research progress in the field of Information Communications Technology (ICT) has an important influence on everyday life, with an increasing number of devices present in the human environment. Existing communication networks and their successors, like 5G, enable the development of a smart home environment, where all these devices communicate and integrate into one system, with the objective to ease and support human life. The population in developed countries is aging fast. This will result in an increased ratio of elderly persons who will need additional care. The smart home environment can provide one of the solutions to prolonging the independent life of the elderly and, in addition, simplify the organization for caregivers from the point when they can't live independently anymore onwards.

A broad set of various services can be implemented in a smart home environment, with the objective to improve the quality of life of the inhabitants. A basic set of services is oriented toward establishing a fully automated and energy-efficient home environment. An extended set of smart home services includes fusion of different information and media content sources into a common platform, which serves as a virtual assistant. The interaction with the assistant can be carried out in an almost natural way if embodied conversational agents (Rojc et al., 2017) are implemented in this role. One of the key pieces of information needed for successful operation should answer the question if users are present in the environment. A smart home environment must be able to monitor the users inside the home, to be aware of their presence and movements in particular rooms.

The presence detection systems in a smart home environment can be implemented in various ways. The basic concept behind presence detection is to measure some of the biological, technical or environmental conditions, which are influenced or generated by the users who are present in the smart home. From the quality of experience point of view, users prefer those presence detection systems which are non-invasive. In the opposite case, users have to carry with them a presence device, which reduces the perceived smart home experience significantly. The presence device can be a dedicated hardware module, which is, typically, using one of the in-door positioning methods to sense the user's presence. Wireless systems like RFID, NFC, Bluetooth, Bluetooth Low Energy (BLE), etc. have been applied successfully for this task. Another approach is to use some terminal equipment that users are carrying with them as a presence device. Nowadays, a smartphone is best suited for this task, although it still has to be carried by the users all the time to fulfill the role of the presence device, which reduces the comfort of smart home inhabitants.

DOI: 10.4018/978-1-7998-3479-3.ch011

The non-invasive methods for presence detection in a smart home can be classified according to the modality which is being measured or monitored to detect the user's presence. A frequently used approach is based on Passive Infra-Red (PIR) motion detection sensors. The PIR sensor is a small electronic device, which operates locally and detects the increased level of infra-red light radiation emitted by humans. Another solution is based on acoustic presence detection, which estimates the users' presence based on uttered words and other sound produced by the speakers during their presence and activities in the environment of a smart home. In this case, the audio signal is captured by a single microphone or by a microphone array, and processed to detect users' presence with audio and speech classification algorithms. A similar approach can be carried out using the visual modality, where a video camera captures a signal and the user's presence is detected with visual object recognition algorithms. An example of the non-invasive presence detection method, which is measuring technical conditions, is based on estimating the change in the electromagnetic field using IEEE 802.11 Wi-Fi access points.

The objective of the proposed encyclopedia article¹ is to present the approach of acoustic presence detection in a smart home environment, analyze the modules which are building the complete system, and propose the key elements for the given context. The acoustic presence detection solution benefits greatly from Human-Computer Interfaces, which are part of intelligent ambient. The usage of acoustic presence detection in a smart home environment is one of the building blocks which is a prerequisite for establishing a natural user-interface for human users.

BACKGROUND AND LITERATURE REVIEW

In the area of presence detection for the smart home environment, passive infra-red sensors are the method which has been applied most frequently for a user's presence detection (Monaci and Pandharipande, 2012). The main reason is its low technical complexity and low costs. The methods based on video modality (Ahvar et al., 2016) were used successfully for presence detection in different smart home set-ups, despite their computational complexity. The third method for sensing a user's presence in the environment is based on acoustic signals. Acoustic presence detection can be carried out with different algorithms. One of the simplest is based on measuring loudness in the smart home environment (Brgulja et al., 2010). More robust and accurate are methods based on low-level features, like the ones extracted by the openSMILE toolkit (Eyben et al., 2013). The most sophisticated acoustic presence detection systems are using classification or recognition algorithms, which are processing acoustic signals captured in a smart home environment by microphone arrays.

Smart environments contain various electronic devices that allow us to interact with human and machine. For detection of the acoustic presence we need a microphone for capturing an acoustic signal in such environments. The installation of the selected microphone in the room is not self-evident, because we need to know the acoustics of the room. The book (Virtanen et al., 2018) provides an overview of the methods for computational analysis of sound scenes and events for different environments, while sound environment analysis in a smart home was provided in (Sehili et al., 2012). The main approach for capturing sound in a smart home environment is microphone array. The study and implementation of microphone arrays are explained in detail in (Brandstein & Ward, 2001). The audio signal captured with microphone arrays is the basis for further steps of acoustic presence detection in smart home environments that can contain different types of acoustic signals, from speech, music, various noises from the environment, and, of course, also a signal of pure silence. If the goal is to detect the presence of a human, then pre-processing techniques must be used to remove the noise from the captured audio signal,

while the music in the background is also intended to be noise. Most of the pre-processing algorithms will work well if a good noise estimate can be provided. This can be achieved by using Voice Activity Detection (VAD) algorithms. The VAD algorithm excludes parts that contain only noise. In this way, a good estimation of the noise characteristics can be obtained, which is then used in the noise reduction procedures. Noise reduction techniques are well presented in the book (Vaseghi, 2009), while a comprehensive presentation and comparison of VAD algorithms is given in (Stadermann, 1999). The VAD algorithm also plays an important role in the classification process, as it removes parts of the captured audio signal that contain noise. In the classification process, therefore, it is not necessary to process the entire captured signal, which makes the classification less computationally demanding and more accurate. Before the classification process, it is also necessary to select the optimal features that will contribute to a good classification result. Most of the feature extraction algorithms are given in (Gupta et al., 2018).

The end result of acoustic presence detection is given by the classification task, which belongs to the area of machine learning and statistical modeling. The classification which is part of acoustic presence detection is frequently based on classification approaches also applied in the area of automatic speech recognition (Junqua and Haton, 2012) and acoustic analysis (Zöhrer and Pernkopf, 2016). Gaussian Mixture Models (GMM) are an example of classification methods which were applied successfully for many scenarios. GMMs were used for classification of speakers' characteristics (Mallouh et al., 2018), such as gender, age, speaking style, etc. The GMM classification approach was also used for language identification (Anjanendu et al., 2018) and music identification (Chaudhary et al., 2019). A related approach (Benzeghiba et al., 2007), used widely for a similar group of tasks are Hidden Markov Models (HMM). HMM are, in the first place, used for speech recognition, but can be also trained for other scenarios (Ma et al., 2006). Deep Neural Networks are currently the state-of-the-art approach for classification of various acoustic categories (Mesaros et al., 2018), and can also be applied successfully for acoustic presence detection in a smart home environment.

ACOUSTIC PRESENCE DETECTION

The next section will present the functionality and interoperability of acoustic presence detection in the smart home environment from the system point of view (Figure 1). The first step is a good capture of the audio signal, which can be achieved with a good microphone array. However, in the captured audio signal is not present only speech, therefore it is necessary to define the areas where the speech signal is located. For this matter, a voice activity detection algorithm is used. From the captured speech signal, it is necessary to define robust features with the feature extraction algorithm, which will be most appropriate in the classification process for the acoustic presence detection. The classification process takes into account the input feature vectors and the information collected in the acoustic model in a statistical way and then classifies the input signal in the predetermined classes. In the following subsections, each building block will be described in more detail.

In a smart home environment, the presence of people can be detected by capturing a video signal or by capturing an audio signal with different types of microphones. Most people do not feel comfortable in the presence of video cameras, therefore, in smart home environments, the detection of people's presence at the acoustic level of audio signal processing is often preferred.

Acoustic presence detection belongs to the group of non-invasive methods, as no dedicated user's device is needed, which is one of its main advantages. The next important advantage over other methods is that acoustic presence detection also works without direct line-of-sight contact with the user. Thus, it

Figure 1. Acoustic presence detection block scheme

is easier to cover larger areas in the smart home, especially in the case when the rooms are of irregular shape. The acoustic presence detection is also capable of operation in adverse visual conditions (e.g. darkness, low-visibility), where it outperforms systems based on video modality. Another advantage of acoustic presence detection is connected with the system resources needed for operation. Basic acoustic presence detection can work locally, with a limited amount of system resources, which can be provided by an embedded system. The main disadvantage of acoustic presence detection is the fact that it collects the user's spoken interaction and, thus, interferes with the user's privacy. Another disadvantage of acoustic presence detection is connected to various environmental sounds (e.g. background conversation, music streaming, TV, etc.) which are present in the smart home environment and decrease the acoustic presence detection accuracy.

Capturing Signals in a Smart Home Environment

The best results of capturing an audio signal can be achieved by close-talking microphones, but, in smart home environments, this is not useful. In addition, these microphones can be used to develop such systems and to capture reference data. Microphones which do not disturb people are usually placed as a device with a microphone array that captures the audio signal well in the entire room. There are quite a few devices on the market that allow the capture of an audio signal in the room. Figure 2 shows a visual presentation of some of these devices. Below we will do a review of these devices and give an opinion on their use.

Figure 2. Devices with microphone arrays – a) Voice Tracker I from Acoustic Magic, b) Voice Tracker II from Acoustic Magic, c) VPM220 Microphone Array from Huawei, d) Condor Beamforming Array Microphone - MT600 from Phoenix Audio Technologies, and e) Beamforming Microphone Array from ClearOne

The Voice Tracker I (Figure 2.a) (Voice Tracker I, 2018) and the Voice Tracker II (Figure 2.b) (Voice Tracker II, 2018) are produced by the manufacturer Acoustic Magic. They differ in the number of microphones used. The first one uses eight microphones in the length of 45.7 centimeters, while the second one uses six microphones in the length of 25.4 centimeters. The Voice Tracker I has the ability to capture signals up to nine meters, while the Voice Tracker II allows the acquisition of a signal at a shorter distance up to six meters. Both operate in the frequency range between 100 Hz to 11,250 Hz. The VPM220 Microphone Array (Figure 2.c) (VPM220 Series, 2018) is produced by the manufacturer Huawei. This microphone array allows reception of the signal up to a distance of six meters, and its operating frequency range is between 100 Hz and 22 kHz, which is the best of all the devices presented. The Condor Beamforming Array Microphone - MT600 (Figure 2.d) (Condor MT600, 2018) from the manufacturer Phoenix Audio Technologies, uses 15 microphones in the length of 122 centimeters. The range of capturing the signal of this microphone array is nine meters and the operating frequency range is between 50 Hz and 16 kHz. The last of the analyzed microphone arrays is Beamforming Microphone Array (Figure 2.e) (Beamforming Microphone Array, 2018) from manufacturer ClearOne, which uses 24 microphones in the length of 76.2 centimeters. Its range of signal capture is up to three meters, which is the shortest distance between the analyzed microphone arrays, and operates in the frequency range between 150 Hz and 16 kHz. In our opinion, for this microphone array, the lower frequency range is slightly too high, especially if we want to detect the presence of a speaker based on the pitch value of the speaker. All the microphone arrays compared can operate independently, except for the VPM220 Microphone Array (Figure 2.c), which works only in coexistence with the Huawei TE Series HD Videoconferencing Endpoints (TE Series HD, 2018).

Each of the manufacturers suggests the best place to install their device in order to work optimally. Some of the proposed microphone arrays are installed on the conference table, another on the wall, and the third can be placed on the ceiling of the room. The above-mentioned devices have different lengths of reception of the speech signal, so it is not necessary that each device covers the entire room, especially if we have a larger room in mind. The question arises as to how to capture the speech signal well even in the corners of the room itself, and not just near the microphone array. It is useful to detect the presence of the user when he enters the room with the smart environment. Therefore, it would be appropriate for

microphones to be installed at the entrances to the room. The microphones can be placed in devices such as the light switches. In such installation of the microphones room acoustics are especially important. In the next paragraph, we will give guidance on what we need to consider room acoustics successfully, especially when there are several microphones installed in the room.

One of the most important criteria for recording sound in a room is the room's geometry itself. In addition to the shape of the room, the room's volume, the arrangement of furniture and the materials used in the walls, ceiling, floor, and the furniture are also important. Different materials have different absorption characteristics that can suppress the sound level of the audio signal greatly. The contrast of the absorption of the signal is the reflection and also the scattering of the audio signal on various materials, which can, additionally, introduce distortions of the signal source. How to deal with room acoustics is presented in more detail in (Kuttruff, 2017).

Pre-processing, VAD and Feature Extraction

Once an audio signal is captured, it is necessary to use an effective Voice Activity Detection (VAD) algorithm, which detects the areas of speech in the audio signal. The VAD algorithm can basically distinguish between speech which is mixed with background noise and the background noise itself. In order to achieve the best possible operation of the VAD algorithm, various pre-processing techniques of the captured speech signal must be used. We can use various procedures for speech enhancement and noise reduction, which can improve the quality of the speech signal. These procedures are based on Wiener filtering and spectral subtraction. If, however, we capture a speech signal using a large number of microphones, we can also use techniques such as source separation, channel identification, or speech de-reverberation. All these procedures are described in detail in (Huang et al., 2006).

Existing VAD algorithms try to distinguish between speech and noise based on the information they receive from the frames. In order to use conventional methods of signal processing, it is useful that the signal within a frame is stationary. This can be ensured if the frame duration is between 20 and 30 milliseconds. The result of voice activity detection is the binary value that represents information on whether the input signal contains speech (e.g., the output is 1) or only noise (e.g., the output value is 0). Below, we will make a review of the VAD algorithms from those simple to the more complex ones, which use different features that help to make the right VAD decision.

Most VAD algorithms use features that are based on the calculation of energy or power in the signal. However, since it has been shown that the use of energy as the only feature brings worse results, especially in low signal-to-noise (SNR) environments, in many cases, other features are added. One of these is the zero-crossing rate criterion, which is used in (Kotnik et al., 2001). In combination with the energy of the frame it has improved voice activity detection. The use of the autocorrelation function over the frequency spectrum of each frame also contributed to the improvement of the VAD activity (Vlaj et al., 2004). Some VAD algorithms use as a feature the distance between cepstral features (Haigh & Mason, 1993). In (Renevey & Drygajlo, 2001) spectral entropy was used as a feature. The Gaussian probability distribution model presented in (McAulay & Malpass, 1980), and then used in (Ephraim & Malah, 1984), is the basis of the VAD algorithm based on the statistical model (Vlaj et al., 2012). In (Price et al., 2018), neural networks are used to decide on the presence of speech. In (Zou et al., 2014), the Linear Predictive Cepstral Coefficients (LPCC), that were determined on the basis of autoregressive modeling, were used to decide VAD. In all of the aforementioned VAD algorithms, information was used from the time domain or from the frequency spectrum domain. The presence of the speech area in the audio signal is then given by the VAD decision as shown in Figure 3. In (Eshaghi & Mollaei, 2010), the

Figure 3. Captured audio signal in time and frequency spectrum domain and the area where only the speech signal is present based on the VAD decision

characteristics of the VAD algorithm are derived from the spectrum obtained by the wavelet transformation. VAD algorithms that use higher-order statistics are among the more complex ones (Li et al., 2005).

Most of these VAD algorithms have their advantages as well as weaknesses. Thus, VAD algorithms based on statistical models (Vlaj et al., 2012; Wu et al., 2018) and neural networks (Price et al., 2018) can achieve good results, but they are quite dependent on the training set needed for the model or network to be well trained. Of course, if we have a good training set that is well segmented (the borders between the speech signal and the noise are correctly set), we can get very good results with statistical models and neural networks. For a good segmentation, however, it is usually necessary to annotate the training material of the speech database manually. Recently, attempts have been made to achieve voice activity detection through the help of multimodality (Ariav & Cohen, 2019).

Since the VAD decision is made on the frame bases (for example, the duration of one frame is 25 milliseconds), frequent switching between one and the other decision can occur. Therefore, it is reasonable that in smart home environments we capture the signal at longer time intervals, for example, 250 milliseconds. This solution has proved to be very effective in defining the beginning and ending boundaries of the speech signal in speech-based platforms for intelligent environments (Kos et al., 2018). In the following, we will explain briefly the idea of capturing signals. The speech signal is captured every 250 milliseconds and is saved temporarily in a circular buffer. This 250 millisecond signal is then cut into 20 sub-frames, with 50 percentages overlap. Then, the process of voice activity detection is performed in each of the 20 sub-frames. We can use any of the VAD algorithms that make the decision on the frame basis. If more than 10 sub-frames are detected as speech, the whole frame is recognized as speech; otherwise, the whole frame is recognized as silence or noise. The resulting segmented signal is the first of the indicators for acoustic presence detection in a smart home environment. However, if we want to find out who is present in such an environment, then we have to use the classification methods.

Before the classification procedure it is necessary to create features which are most appropriate for the acoustic presence detection of a speaker in a smart home environment. The speaker can be an adult (male or female) or a child. The feature extraction procedure is a key factor to successful gender or age

classification. Various approaches, such as Mel-Frequency Cepstral Coefficients (MFCCs) (Gaikwad et al, 2012; Yücesoy & Nabiyeu, 2013), prosodic features like pitch (Ramteke et al., 2018), were used for the gender classification task. Also, paralinguistic features, such as speech rate, voice quality, pauses, can be applied successfully to the gender classification task (Mueller, 2006). In other types of classifications, which were not used for gender or age classification but for the classification of human activities in natural environments, features were used such as MPEG-7 Low-Level Descriptors (Ntalampiras et al., 2012) and Perceptual Wavelet Packets (Ntalampiras et al., 2009). After reviewing all the feature extraction algorithms, we would select MFCCs, because in our opinion it would be best appropriate for acoustic presence detection. MFCCs are determined using a discrete cosine transformation from logarithmic values of Mel-filter banks ($\log Fbank$), as determined by the equation below. In this case, K represents the number of MFCCs and J the number of logarithmic values of Mel-filter banks.

$$MFCC(i) = \sum_{j=1}^J \log Fbank(j) \cdot \cos\left(\frac{\pi \cdot i}{J}(j - 0.5)\right) \quad 0 \leq i \leq K \quad (1)$$

Acoustic Classification Procedures

The main objective of the classification task is to distinguish between different acoustic categories present in the signal captured from the smart home environment. In the case of acoustic presence detection, at least two classes must be defined. The first one determines the presence of the human user(s), according to the spoken signal, and the second one determines the presence of silence, which indicates the absence of the user. Acoustic presence detection systems are deployed frequently in an intelligent ambient, where other sources of audio also exist. One such example of audio sources is the user's media devices, like TV or home entertainment/music system. An audio signal produced by them can be misclassified as the user's signal, and, as a consequence, misinterpreted as a user's presence by the smart home main control and the decision module. One of the possible solutions to reduce the proportion of such misclassification is to introduce an additional separate class, which determines the various audio background effects which can frequently be found in the user's environment. In this case, it is beneficial if the type of user's environment can be specified precisely, as the categories of acoustic background events and sources differ highly between them.

Acoustic presence detection can be applied in conjunction with automatic speech recognition, as the key elements share a large portion of algorithms. We will, thus, first present classification approaches which are also used frequently in the domain of human language technologies. Gaussian Mixture Models (GMM) are a statistically based approach. Each acoustic class has its own separate GMM model, which is defined as:

$$p(x) = \sum_{i=1}^K \phi_i \mathcal{N}(x | \mu_i, \sigma_i) \quad (2)$$

The GMM model is defined by a mixture of Gaussian probability density functions, where weight ϕ_i specifies the impact of each particular probability density function. The function is defined by its mean value μ_i and variance σ_i . The total number of mixtures used in a GMM depends on two factors. The first one is the amount of acoustic training material belonging to a particular audio class. The second

one is the distribution and sparseness of extracted feature vector values in the multi-dimensional feature space. Typical GMM models can have several 10 to several 100 probability density functions. During the classification procedure, each acoustic frame with feature vectors gets classified, to estimate, which acoustic class it belongs to.

The output of the classification approach is a stream of classes' labels, where short glitches are also present. In the case of a smart home environment, such short glitches usually present misclassified input, as it is highly unlikely that the user leaves the monitored area for as short a duration as 10 or 20 ms (a glitch with a duration of 1 or 2 input windows). To minimize this effect, a post-processing procedure can be applied to the output stream of labels, which is used to smooth out these short glitches.

Another classification approach, which has its origins in the field of automatic speech recognition, is based on Hidden Markov Models (HMM). The HMM approach also belongs to the category of statistical modeling. A left-right models' topology with continuous Gaussian probability density functions is being used for acoustic modeling. The number of states per model varies between 2 and approx. 10, and it depends on the characteristics of the acoustic data used for training. The HMM acoustic models are defined as:

$$\lambda = (A, B, \pi) \quad (3)$$

Where λ denotes the HMM model, A denotes the transition probability between state i and the next state j , B denotes an observation probability matrix, and π denotes the initial state distribution. Each HMM state is modeled by a continuous density probability function. In the case when a Gaussian function is applied, the weight ϕ_i , mean value μ_i , and variance σ_i define the function. The Baum-Welch re-estimation procedure is applied for training the acoustic models. The trained acoustic models are used for classification with the Viterbi decoder, which estimates the maximum probability that the input feature vector results in a particular acoustic environment class. The estimation takes place on larger parts of the input signal, which are homogenous from the voice activity detection point of view. As a consequence, the short glitches, which are present in the case of GMM classification, are absent in the case of HMM modeling, which presents an advantage over the method presented above. An additional advantage of HMM modeling is that it can share modules with automatic speech recognition if this uses the same architectural approach. The disadvantage over the GMM method is its computational complexity, which is higher than for the GMM approach.

With the availability of larger acoustic data sets and multi-core Graphical Processing Units (GPU), various deep learning methods could also be applied for the acoustic presence detection task. One of the most commonly used ones is Deep Neural Networks (DNN). In this case, each acoustic class is needed for presence detection, represented by a neural network. Recently (Xia et al., 2019), the convolutional neural networks (Valenti et al., 2016), which originate from the area of image processing, present the most advanced approach for acoustic classification. In this case the log-mel spectrograms are used to present the input audio signal. The ensemble method (Xu et al., 2018) provide a way, how different classification approaches can be successfully combined in a complex solution with increased accuracy.

A classification approach which has its origins in other areas of machine learning is Support Vector Machines (SVM), which belongs to the category of supervised learning models. The extracted feature vectors are, in the case of SVM, grouped in classes in a way to build groups separated by a hyperplane in a multidimensional feature space. The objective is to maximize the distance between the hyperplane and the nearest feature vector element.

The advantage of acoustic presence detection is also its ability to use the input speech signal to extract other important information, which is given in the uttered speech implicitly or explicitly. In the case when, besides the acoustic presence, the system also detects other users' characteristics, more detailed separation is needed of acoustic training material. An example of implicit information given in the uttered speech which can be then classified is various speakers' characteristics. The more interesting ones belong to a demographic category, such as the speaker's gender and/or age. This information can be valuable in a smart home environment, as it could give an additional value to assisting services and human-computer interfaces.

The inclusion of more information in the acoustic presence detection system requires increased complexity of classifiers. The most straightforward approach is to increase the number of modeled classes according to the classification task. Another approach is based on system fusion, where different classifiers are combined to provide one final decision regarding the output result. The explicit information given in the uttered speech signal is the textual information. This one can be processed with an automatic speech recognition system, which is part of the advanced human-computer interface in a smart home environment. As the end result, the automatic speech recognition output also gives valuable information about the speaker's presence. The decision whether to use automatic speech recognition as a form of acoustic presence detection, should bear in mind the user's privacy concerns, which are still important, despite the wide usage of different social networks and new methods of communication.

SMART HOME SERVICES BASED ON ACOUSTIC PRESENCE DETECTION

Services represent the key results of the smart home environment. To be able to improve the services' operation, advanced functionalities are required. One such example is the customization of available media content according to the detected user's age, which can be used as a type of parental content control for children. The speakers' demographic characteristics can be also used in other types of intelligent ambient modules, which have to deal with the media or information. The media content recommendation system, which is frequently included into a video on demand service or music/radio streaming service, can benefit from information about the user's age and gender information, each time the system must be initialized or cold-started. A further example is when the recommendation system must operate without the explicit knowledge of the user's identity, or in cases when it operates in a public or private environment where the users' population changes frequently. Virtual assistants are one of the possible human-computer interface services in the smart home, which provide a way of natural communication to the users. The user's characteristics can be important additional information for a virtual assistant, especially in those cases where the virtual assistant uses only the tactile and/or haptic input modality. In the case when an embodied conversational agent gets applied in the role of the virtual assistant, this information can be used for the initial part of the communication, or, in cases when the degraded acoustic environment reduces the accuracy of direct audio input signal to the embodied conversational agent.

Another example of advanced services' functionality is the personalization of a graphical user interface in a way to use larger icons and font size in the case when the acoustic presence detection system classifies the input audio signal as one belonging to an elderly person. A more sophisticated version of an acoustic presence detection system can run a speaker detection system, which could detect the particular user in the monitored environment. The drawback of this solution is its complexity, and the fact that, for a typical home scenario, the method produces too detailed information, as the same personalization/customization result can be achieved using simpler methods and characteristics, even without collect-

ing sensitive personal information. The typical smart home users prefer the approaches where their personal information, including voice signals, are processed locally, without the need to be uploaded to the cloud-based infrastructure for further processing. An additional benefit is also the possibility to develop the architecture as a stand-alone system, with the possibility to carry out the operation, even in the case when the internet connection suffers from black-out.

DISCUSSION AND FUTURE TRENDS

After analyzing the characteristics of the compared audio capture devices, the Condor Beamforming Array Microphone - MT600 from manufacturer Phoenix Audio Technologies selection would be proposed to capture the audio signal up to nine meters, and has a wide frequency range between 50 Hz and 16 kHz. This is the only microphone array that has a lower frequency limit set to 50 Hz. Such low limit also makes it possible to determine the pitch value of men with a deeper voice. The microphones, that should be placed in the switches, must be able to capture an audio signal in a similar frequency range. We also propose the use of the VAD algorithm, which would, in smart home environments, allow decisions on the presence of speech in the captured signal over extended time, such as 250 milliseconds. For the classification procedures, according to the experience of the previous research, we would propose the use of features that would be determined from the combination of Mel-Frequency Cepstral Coefficients (MFCC) and MPEG-7 Low-Level Descriptors.

The future trends in the area of classification will be oriented toward providing advanced classification algorithms for acoustic presence detections which are capable of operating in a distributed way on low-resource devices, such as embedded IoT systems in wireless acoustic sensor networks. This aspect of smart home environment processing is particularly important from the point of view of taking care for the user's privacy and, consequently, establishing a processing system where all personal information gets processed locally.

CONCLUSION

The article presented details methods of how the user's presence in a smart home environment can be detected from the acoustic signals produced by humans. First, the solutions were analyzed and presented to capture high-quality acoustic signals. The focus was given to different microphone arrays, which clearly outperform single-channel stand-alone microphone solutions. The next important step is oriented toward improving the robustness, and to extract features present in the captured acoustic signal. The last part presents the classification of users' presences, or, in the case of advanced systems, to determine additional users' characteristics.

The acoustic presence detection based on advanced classification approaches can provide information on users' presence successfully to the main smart home module, where other services then benefit from this additional knowledge. This is important for improving the quality of experience in the smart home environment, as services' personalization and customization can be carried out.

KEY TERMS AND DEFINITIONS

Classification: An approach to separate data into classes.

Feature Extraction: An algorithm to extract distinctive values from signal.

Microphone Array: Acoustic capturing device, which combines multiple microphones.

PIR Sensor: Presence detection sensor, based on infra-red light.

Room Acoustic: Acoustic characteristics of an environment.

Smart Home: An advanced living environment, where ICT solutions support inhabitants.

VAD: An approach of detecting speech in signal.

INTRODUCTION

It is generally well established that a good many phenomena of everyday life are quite complicated to be described in a simple, concise and quantitative way. Many examples can spring to mind; from the motion of an object in the Earth's atmosphere to the (long term) weather forecasting, or from bacteria growing experiments in a Petri plate to space craft missions, etc. Indeed, almost all the physical (real) systems, say from natural sciences (e.g., physics, chemistry, biology, geology etc.) to applied sciences (e.g., engineering, economics etc.), and from health sciences to humanities are susceptible to a – more or less – multi parametric and complex prototype.

The aforementioned complexity is due to the following reason: The magnitude of the system under consideration is beyond any reasonable reach and completely unlikely to be reproduced in the laboratory for study

- a) either at a local level; indeed, for example, although it is quite simple to deal with the motion of a gas molecule, it is extremely difficult for a human to do the same with the motion/behaviour of an enormous amount of molecules interacting with each other;
- b) or at a global level, for example, the weather forecast in meteorology, the galaxy collisions in Relativistic Astrophysics, etc., for obvious reasons.

Conceptually, case (a) is by default attacked by implementing statistical methods, while case (b) is attacked by multi parametric analytical systems. Nevertheless, both cases are dealt with the use of computers. In other words, the previously mentioned multi parametric, complex prototype is realised as a (imperative) computer code of a functional nature: some input is given and an output is expected (thus the imperative character); also same inputs produce same results (hence the functional character). This computer code incarnates the term “*computer simulation*” [see (Osais, 2017) for an overview of the programming aspects of simulation].

Definition 1. A computer simulation is a computer program that represents the dynamic responses of one system by the behaviour of another system modelled after it.

BACKGROUND

Computers can be used to simulate physical systems but is the use of computers (and thus the need for computer simulations) something unavoidable? The answer to this question is affirmative.

Indeed for the case (a), general theorems from Statistics dictate that the larger the magnitude of the prototype the more accurate and with less deviation is the forecast for the behaviour of the system. Within this sector of this type of problems the need for the use of random numbers (expressing an arbitrary possible state of the system) is a *sine qua non*. Of course, it is practically impossible for a human to produce massively random numbers and thus to emulate a plausible (physical) state of the statistical system under consideration. At this point the computers enter the study; they can produce in (almost/relatively) no time huge quantities of arbitrary numbers, therefore they suffice for the description of the collection of physical states. Yet, there are two limitations here:

- On one hand, computers produce pseudo random numbers and not completely random ones. This has to do with the whole concept of what a human made machine is capable of. Modern techniques have been tried to smooth away this problem by implementing characteristics of the machine (like the temperature of the CPU or the “entropy” of the accumulated information etc.) which could be used to produce truly random numbers, but the very essence of the problem remains since in any case correlating functions are involved.
- On the other hand, computers do not cope well with real numbers, but only with integers. Thus, two real numbers which are supposed to be equal, do not have their difference equal to zero but rather equal to a given (very) small number. For instance, 0.99999 and 1 can be consider as equal (if the tolerance/accuracy is, say, 0.00001) or not –depending both on the hardware architecture and the software constraints.

Now, for the case (b), the arguments go as follows. There exist systems:

- § which either it is beyond any hope (for various objective reasons) for them to be reproduced in the laboratory and thus to study all the aspects/parameters of the problem, for example, the collision of two black holes in Relativistic Astrophysics or
- § which can be considered as showing extreme behaviour that belongs to the limits of a theory. In this case, it is possible for those limits of the theory/prototype under consideration to surpass the current technical abilities. Then, a computer based prototype can fill in the gap between current technology and theoretical demands/inquiries.

Again, as before, the aforementioned limitations are still valid plus one more; the accuracy of the computer based prototype –leaving aside the issue of potential human errors.

Thus, the general conclusion is that for various different reasons, depending of the case under consideration, the implementation of computer simulations is of fundamental importance.

Let us present a naive example that can serve as a comprehensive illustration of the need for computer simulations.

The Problem: *the study of the electromagnetic radiation near the accretion disks in the vicinity of a black hole* [see (Thorne, 1994) for an accessible account of black holes and (Romero & Vila, 2014) for a recent account of the physics of black holes].

The Solution: (towards the computer simulation)

First, one chooses the underlying theory which will describe the physical phenomenon. This theory is going to be the General Relativity and the space will be parameterized by the Kerr space time geometry. The needed equations (i.e., the actual prototype) are the geodesic equations (i.e., equations describing the generalised “straight” lines in a curved space) – a set of entangled, non linear, ordinary differential equations of the second order on the Kerr background. Thus the conceptually fundamental quantity here is the notion of the derivative (say, with respect the “time” variable).

Second, one has to consider how to realise the notion of the time derivative in a manner proper for a routine treatment. The basic idea is to consider space as a discrete net endowed with a tessellation of given (say) cubes. The edges of the cubes correspond to the three spatial coordinates while the position of a cube on the net determines the time coordinate. The discrete character is very important for two successive points on the net will correspond to a difference of two given cubes, that is, the derivative of space coordinates with respect to time. This procedure is called the discretization *of the continuum* (in general, discretization is the process of transferring continuous functions, models, variables, and equations into discrete counterparts).

Next, the fundamental equations (i.e., the geodesic equations) assume a much more ugly –yet completely “comprehensive” by the computer– form; they become sequences of discrete differences on the net. In fact this very nature of those sequences guaranties the imperative and the functional character of the computer simulation. Now one is ready to provide some initial and/or boundary conditions in the form of data concerning the spatial coordinates and their first time derivatives (i.e., velocities) at specific areas of the net. Then, what one has to do is just to observe the (“time”) evolution of the system in the form of the sequence terms on the net.

In what follows we are going to present a number of simulation technologies that are useful per se or can be used to solve real life problems. In addition, we are going to discuss the necessity of quantum computing and the limits of simulation. We will conclude with a brief description of the Simulation Hypothesis.

ARTIFICIAL LIFE

Artificial life is a form of computer simulation that is often used to study essential properties of living systems that include evolution and adaptive behaviour [see (Adami, 1998) for a rather complete overview of the field]. Artificial life is a field that owes its name to the American computer scientist Christopher Langton. This field covers a wide range of disciplines, from engineering over biochemistry to physics, biology, and computer science. The ultimate goal of artificial life is to understand the general principles that govern living beings, and to construct life in an artificial medium so that its properties can be compared to life with which we are familiar. Naturally, as a field that is essentially a form of simulation, artificial life aims to show that modern technology can help us to understand life as a phenomenon. Since each scientific field require some sort of foundations, artificial life is no exception and its roots are in Turing’s Automata Theory and the logical, self-reproducing automata of von Neumann. John Horton Conway created a fantastic solitaire game he called “Life” [see (Gardner, 1983) for an accessible description of the game].

A cellular automaton is a feedback machine that consists of an array of cells. These arrays are either one-dimensional, in which case cells are lined up like a chain, or two-dimensional, in which case cells form a grid. The Game of Life is actually a simulation game because it resembles the evolution of a society of living organism. The evolution rules of the Game of Life are based on the following principles:

- i. There should be no way to tell beforehand whether the population can grow without limit.
- ii. It should be possible to set up a system that apparently grows with no limit.
- iii. After some initial growth a population should fade away, settle into a stable state and remain unchanged thereafter, or it should enter an oscillating phase in which it repeats an infinite cycle of two or more periods.

These rules make sure that the behaviour of the population will be interesting and unpredictable. The evolution rules follow:

- i. Every cell that has two or three alive neighbours survives for the next generation.
- ii. A cell that has four or more alive neighbours dies. Also, if a cell has only one neighbour or no neighbours dies from isolation.
- iii. A dead cell that has three or more alive neighbours is resurrected.

GENETIC ALGORITHMS

One natural phenomenon that is most frequently tackled today is evolution: What are the principles by which life produces new, more complicated and more fit life forms that replace existing ones? Evolution is something that is of paramount interest to biologists but engineers are also interested to it mainly because they would like to realize evolutionary technologies that could create better tools and machines from existing ones.

Genetic algorithms are common computational model that (tries to) mimic evolution in order to solve a number of problems. In general, a computational solution of a problem can be perceived as a search through a space of potential solutions. Clearly, we are interested in the “best” solution, thus a computational solution can be seen as an optimization process. When the solution space is large, one has to employ “clever” techniques. One such technique is the genetic algorithms. These algorithms are stochastic processes that model genetic inheritance and the clash of species and individuals for survival [see (Michalewicz, 1996) for a classical exposition of genetic algorithms]. An *evolution program* implements a genetic algorithm. An evolution program maintains a population of individuals,

$$P(t) = \{x'_1, \dots, x'_n\},$$

for each iteration t . Each individual represents a solution to the problem and it is evaluated to see how fit it is. Then, a new population is generated by selecting the more fit individuals and by modifying certain individuals using some sort of “genetic” transformation. Below we give the general structure of an evolution program as it appears in (Michalewicz, 1996):

```
void evolution_program(void) {  
    t = 0;  
    initialize(P(t));  
    evaluate(P(t));  
    while (! terminal_condition) {  
        t++;
```

```

select P(t) from P(t-1);
alter(P(t));
evaluate(P(t));
}
}

```

SWARM INTELLIGENCE

One could say that *swarm intelligence* (Kennedy & Eberhart, 2001) is about intelligence being social. An extreme example of this social intelligence is the brain of a typical human. The brain is composed by approximately 86,000,000,000 neurons (i.e., brain cells) and although no single cell is intelligent, the totality of neurons, which make up our brain, is obviously intelligent. However, swarm intelligence is about bee hives and ant colonies. One could argue that emergence, which is roughly the idea that some properties of a system are irreducible, plays a central role in swarm intelligence. Thus an ant or a bee has some intelligence but the insect alone cannot achieve what a particular totality can achieve.

In principle, *difficult problems* cannot be solved so to yield answers quickly, still there are approximate methods that can yield results quite quickly. These methods are not general solutions to problems and are known as *heuristics*. A *metaheuristic* is a set of ideas and concepts that can be used to define heuristic methods applicable to a wide set of different problems. The Ant Colony Optimization (ACO) (Dorigo & Stützle, 2004) metaheuristic is based on the idea that a colony of artificial ants cooperate in order to find good solutions to some sort of difficult problems.

VIRTUAL REALITY

Definition 2. Virtual reality (VR), is a computer technology that replicates an environment, real or imagined, and simulates a user's physical presence and environment in a way that allows the user to interact with it. It is an emerging trend which is now bringing more public attention. (Joseph, 2016)

Clearly, VR can be used to model and to simulate real environments. In addition, one or more persons can interact with these environments using interactive devices that can send and receive information. Typical examples of such devices are headsets, gloves, or body suits. Also, the user is wearing a helmet that allows her to have stereoscopic view of the simulated environment. Thus one feels as if she is inside this virtual environment. For example, a user can climb stairs, open doors, etc. Special data gloves equipped with force-feedback devices allow users to have the sensation of touch.

LIMITS OF COMPUTER SIMULATION

From the discussion so far one may get the impression that anything is possible with computers. One can even go farther and claim that even the whole universe can be simulated by a computer (Hayes, 2003). Roughly, Hayes investigated the possibility to construct a computer program written in some ordinary computer programming language (e.g., Java or C++) capable of simulating the Universe (whatever one perceives as such). He has reached the conclusion that although this is a particularly difficult task,

nevertheless, it is a feasible one. Now, this conclusion has a number of interesting consequences: Let us assume that we have at our disposal a computer capable of running such a computer program. Then, after some (long?) time, one will witness the emergence of intelligent life forms in this virtual universe, which, quite possibly, on one (virtual) day will construct a (virtual) computer program and a (virtual) computer capable of simulating their own virtual universe, etc. Such a story is an ideal for scripts for sci-fi movies (e.g., the movie “The Thirteenth Floor,” see <https://www.imdb.com/title/tt0139809/> for movie details, is based in a very similar idea), but it has nothing to do with reality [see (Syropoulos, [0910.2859] Can we debug the Universe?, 2009) for detailed discussion.]

Being able to study physical systems *in silico* is something that depends on what the real capabilities of (ordinary) computers are. Recently, Ringel and Kovrizhim (Ringel & Kovrizhin, 2017) demonstrated (but not *proved*) that there are quantum systems that cannot be effectively simulated by computers, even quantum computers! Of course, the first part of this conclusion is no news. Pour-El and Richards (Pour-El & Richards, 1989) have shown that there is non-computability in ordinary physical systems, such as wave-propagation. Also, the first person who demonstrated that (ordinary digital) computers cannot be used to effectively simulate quantum systems is the famous American theoretical physicist and Nobel prize laureate Richard Phillips Feynman. Around 1982, he published a paper (Feynman, 1982) where he pondered about the possibility of simulating a quantum system with a computer. Feynman examined whether it is possible to simulate and not to imitate time. He concluded that time cannot be simulated but it can be imitated because the “simulation” involves a transition from one state to another. Next, he examined whether it is possible to simulate probabilities. Feynman concluded that probabilities can be simulated by two different methods—the computation of probabilities by an ordinary system or the use of a probabilistic computer. He concluded that the first approach does not work because of intrinsic limitations of computer hardware. A probabilistic computer can be used to yield some statistical result after running the computer a number of times. The problem is that nature is unpredictable and when one has a large number of parameters it makes no or little sense to employ a probabilistic computer in the hope that on a run it will predict the real probabilities. Feynman concluded that only a *quantum simulator* should be able to simulate Nature. Quantum simulators are now known as quantum computers. In the light of results like those of Ringel and Kovrizhim (Ringel & Kovrizhin, 2017), one can safely conclude that the established notion of computation is not adequate to describe Nature. Problems like this prompted the research community to investigate the construction of both *real* and conceptual computing devices capable of doing more than the established models of computation. This new field is known as *hypercomputation* (Syropoulos, Hypercomputation, 2008), however, we are not going to discuss these ideas in any detail.

THE SIMULATION HYPOTHESIS

The fascination about the abilities of mechanical devices has led many thinkers to ponder about the possibility that we actually live in a computer simulation. We have touched briefly this subject in the previous section but here we are going to elaborate on the idea and its pros and cons. Nick Bostrom (Bostrom, 2003) put forth his simulation hypothesis. More specifically, he argued that

- i. it is very probable that humanity will vanish before reaching a “posthuman” stage;
- ii. it will not be possible to run a significant number of simulations of the evolution of any posthuman civilization; and

- iii. it is very probable that we live in a computer simulation.

Trying to respond to such an argument is particularly difficult because it is similar to trying to convince a believer that there is no God. Even if we show that that no computing device, real or conceptual, can actually simulate physical systems, still one may argue that there are yet to be discovered computing systems capable of any kind of simulation.

SOLUTIONS AND RECOMMENDATIONS

Computers have been used to simulate physical systems for many years. However, there are some quantum systems that cannot be simulated by ordinary hardware and one should expect the wide-spread availability of quantum computers to be able to simulate such systems.

FUTURE RESEARCH DIRECTIONS

We presented work about non-computability of physical systems. The question whether computers (even *hypercomputers*) can actually simulate Nature is open. But another question is also open: Can computers simulate minds? The *Chinese Room Argument* by John Searle (Searle, 1980) has *shown* that computers can simulate minds but they cannot realize minds. This argument goes as follows: Imagine that Anna, who cannot speak or read Chinese, is locked in a room with boxes full of Chinese ideograms. In addition, she has at her disposal a rule book that enables her to answer questions put to her in Chinese. One may think of the rule book as a computer program. Anna receives ideograms that, unknown to her, are questions; she looks up in the rulebook what she is supposed to do; she picks up ideograms from the boxes, manipulates them according to the rules in the rule book, and hands out the required ideograms, which are interpreted as answers. We may suppose that Anna is able to fool an external observer, giving the impression that she actually speaks and understands Chinese. But clearly, Anna does not understand a word of Chinese. And if Anna does not understand although she appears to do so, then no computer will actually understand Chinese just because it is equipped with a computer program much like Anna's rule book. Thus, Turing computers cannot be intelligent.

CONCLUSION

We have discussed the notion of simulation of physical system by computers. We have also presented some techniques that use computer simulation to solve difficult computer programs. In addition, we discussed the limits of computer simulation and the simulation hypothesis. The conclusion is that simulation is a very important and useful tool but certainly not a panacea.

INTRODUCTION

As computer capacities and simulation (e.g., Monte Carlo method) technologies advance, simulation has become the method of choice for modeling and analysis. The fundamental advantage of simulation is that it can tolerate far less restrictive modeling assumptions, leading to an underlying model that is more reflective of reality and thus more valid, leading to better decisions (Lucas et al., 2015). Simulation studies are typically preceded by transforming in a more or less complicated way of a sequence of numbers between 0 and 1 produced by a pseudorandom generator into an observation of the measure of interest. Random numbers are a fundamental resource in science and technology. A facility for generating sequences of pseudorandom numbers is a fundamental part of computer simulation systems. Furthermore, random number generators also play an important role in cryptography and in the blockchain ecosystem. For example, common cryptosystems employ keys that must be generated in a random fashion. A collection of random variables $x_1, x_2, \dots, x_n$ is a random sample if they are independent and identically distributed. All samples of the sequence are generated independently of each other, and the value of the next sample in the sequence cannot be predicted, regardless of how many samples have already been produced.

True random numbers cannot be produced by a deterministic algorithm, and hence, random numbers generated by using a recursive equation are referred to as pseudorandom numbers. Pseudorandom numbers seem random, but in fact, they are not random and perfectly predictable. The purpose of these algorithms is to produce sequences of numbers whose behavior is difficult to distinguish from that of their “truly random” counterparts. The deterministic nature of these techniques is important because it can be reproduced effectively in computations. A facility for generating sequences of pseudorandom numbers is a fundamental part of computer simulation systems. Usually, in practice, such a facility produces a deterministic sequence of values, but externally these values should appear to be drawn independently from a uniform distribution between 0 and 1, i.e., they are independent and statistically indistinguishable from a truly random sequence. Furthermore, multiple independent streams of random numbers are often required in simulation studies, for instance, to facilitate synchronization for variance-reduction purposes, and for making independent replications.

A random number generator (RNG) is an algorithm that starting from an initial seed (or seeds), produces a stream of numbers that behaves as if it were a random sample when analyzed using statistical tests, see L’Ecuyer and Simard (2007) and Rukhin et al. (2010). The RNG is closely related to the Deterministic Random Bit Generators (DRBGs). See L’Ecuyer (1990, 2013) and references therein for more information on RNGs. We describe a portable set of software utilities for uniform random-number generation. It provides for multiple generators (streams) running simultaneously, and each generator (stream) has its sequence of numbers partitioned into many long disjoint contiguous substreams, see L’Ecuyer et al. (2002). Simple procedure calls allow the user to make any generator “jump” ahead/back

DOI: 10.4018/978-1-7998-3479-3.ch013

v steps (random numbers). This is more flexible than provides a pre-computed list of seeds that are pre-determined steps apart. Implementation issues are discussed. The basic underlying generator CMRG (Combined Multiple Recursive Generator) combines two multiple recursive random number generators with a period length of approximately 2^{191} ($\approx 3.1 \times 10^{57}$), good speed, and excellent theoretical properties, e.g., the lattice structure, see Kroese et al. (2011) for a list of desired properties.

BACKGROUND

There are several methods for generating the random numbers, of which the most popular are the congruential methods (mixed, multiplicative, and additive). These congruential methods are fast, convenient, and have good enough statistical properties when their parameters are chosen carefully. The (mixed) linear congruential generators (LCGs) are defined by

$$x_i = (ax_{i-1} + c) \text{MOD } m, u_i = \frac{x_i}{m}, x_0 \in \{1, \dots, m-1\}, i > 0.$$

where m (the modulus) is a positive integer (usually a very large primary number), a (the multiplier) $\in \{0, 1, \dots, m-1\}$ and c (the increment) is a nonnegative integer. This mathematical notation signifies that x_i is the remainder of $(ax_{i-1} + c)$ divided by m . Hence, $x_i \in \{0, 1, \dots, m-1\}$. Thus, random variable u_i is a uniform 0, 1 variable. Note that

$$x_{i+v} = \left(a^v x_i + \frac{c(a^v - 1)}{a - 1} \right) \text{MOD } m.$$

Hence, every x_i is completely determined by m , a , c , and x_0 . The sequence x_i repeats once it returns to a previously visited value. The period of a generator is the length of a generated steam before it begins to repeat. If $u_0 = u_p$ (where $p > 0$), then the length p is called the period. The longest possible period for a LCG is m , i.e., m represents the desired number of different values that could be generated for the random numbers. Hence, the modulus m is often taken as a large prime number close to the largest integer directly representable on the computer (i.e., equal or near $2^{31}-1$ for 32-bit computers). If $p=m$, we say that the generator has full period. The required conditions on how to choose m , a , and c so that the corresponding LCG will have full period are known, see Knuth (1997) or Law (2014).

LCGs are sensitive with respect to the parameters, especially the value of a . When $c > 0$, the LCGs are called mixed LCGs. When $c=0$,

$$x_i = ax_{i-1} \text{MOD } m, u_i = \frac{x_i}{m}, x_0 \in \{1, \dots, m-1\}, i > 0.$$

These LCGs are called multiplicative LCGs. Most existing implementations of LCGs are multiplicative LCGs, because in general the value of c does not have a large impact of the quality of an LCG. Note that if $x_i=0$, then all subsequent x_i are identically 0. Thus, the longest possible period for a multiplicative

LCG is $m-1$. Hence, to increase the period and to obtain a denser lattice which covers the space more evenly, one can increase the modulus m . Furthermore,

$$x_{i+v} = a^v x_i \text{ MOD } m.$$

Most experts now recognize that small LCGs with moduli around 2^{31} or so should no longer be used as general-purpose random-number generators. Not only can one exhaust the period in a few minutes on a PC (personal computer), but more importantly the poor structure of the points can dramatically bias simulation results for sample sizes much smaller than the period length.

One way of extending the basic LCG is to combine two or more LCGs through summation. Another way of extending the basic LCG is to use a higher-order recursion. A multiple recursive random number generator (MRG), which goes from integer to integer according to the recursion

$$x_i = (a_1 x_{i-1} + \dots + a_k x_{i-k}) \text{ MOD } m, u_i = \frac{x_i}{m}.$$

A seed $x_0, \dots, x_{k-2}, x_{k-1} \in \{1, \dots, m-1\}$, where i, k , and m are positive integers, and $a_1, \dots, a_k \in \{0, 1, \dots, m-1\}$. To increase the efficiency and ease the implementation, the MRG algorithm usually set all but two a_i 's to 0. Furthermore, the nonzero a_i should be small. However, L'Ecuyer (2013) points that these conditions are generally in conflict with those required for having a good lattice structure and statistical robustness. See Law (2014) on the lattice structure of pseudorandom numbers. The longest possible period for a MRG is m^k-1 (L'Ecuyer, 1996). Other way of extending the basic LCG is the additive congruential RNG (ACRON). The ACRON sets $a=1$ and replace c by some random number proceeding x_i in the sequence, for example, x_{i-1} (so that more than one seed is required to start calculating sequence). Wilkrmaratna (2008) indicated that the ACRON is a special case of a multiple recursive generator. Other classes of RNGs are available, e.g., twisted generalized feedback shift register generators (Matsumoto & Kurita, 1994; Matsumoto & Nishimura, 1998). See L'Ecuyer (2013) and the numerical algorithms group (2019) for more information on other methods of generating random numbers.

The RNGs discussed so far are by computational methods. Another approach is by physical methods, e.g., Kanter et al. (2010) and Raffaelli et al. (2018). Because the sequence of pseudorandom numbers is in principle predictable, data encrypted with pseudorandom numbers is potentially vulnerable to cryptanalysis. On the other hand, hardware random number generators produce sequences of numbers that are assumed to be unpredictable, and therefore provide the greatest security when used to encrypt data. Thus, this class of random bit generators is commonly known as non-deterministic random bit generators (NRBGs). Today, several physical devices are available on the market incorporate various types of methods to generate random bits or random digits. A comparative list can be found on Wikipedia (2019). Those hardware generators are needed for cryptography, games, lotteries, and in gambling machines, where true randomness is needed. Hardware random number generators generally produce only a limited number of random bits per second. In order to increase the available output data rate, they are often used to generate the "seed" for a faster pseudorandom number generator, which then generates a pseudorandom output sequence at a much higher data rate. These applications usually combine an algorithmic RNG with a small source to inject some true randomness, see, e.g., Crypto Poker Club (2018).

Hardware RNGs are not appropriate for simulation for many reasons. It was recognized already in the early 1950's that physical devices are complicated to install and run, costly, slow, and much more impor-

tantly cannot reproduce the same sequence repeatedly. Reproducibility is very important in simulation experiments, e.g., for comparing systems with common random numbers (Law, 2014) and for program verification and debugging. These drawbacks make it necessary for simulation to use algorithmic RNGs. L'Ecuyer (2010) points out that those physical devices are unnecessary and unpractical for Monte Carlo methods, because deterministic algorithmic methods are much more convenient than hardware devices.

MAIN FOCUS

We discuss the algorithm and implementation of L'Ecuyer's (1999) combined multiple recursive random number generator. A combination of generators can have a much longer period than any of its components. Furthermore, with well-chosen parameters, the CMRG has good structural properties and passes many statistical tests, see Kroese et al. (2011). The CMRG is one of the best general-purpose RNGs that are currently available. A list of classical LCGs and their properties can be found on Karl Entacher's website: <http://random.mat.sbg.ac.at/results/karl/server/>.

Basic Generators

The combined multiple recursive random number generator, which goes from integer to integer according to the recursion

$$x_{j,n} = (a_{j,1}x_{j,n-1} + \dots + a_{j,k}x_{j,n-k}) \text{MOD } m_j; \text{ for } j = 1, \dots, J,$$

$$Z_n = \sum_{j=1}^J (\delta_j x_{j,n}) \text{MOD } m_1$$

$$u_n = \begin{cases} z_n / (m_1 + 1) & \text{if } z_n > 0 \\ m_1 / (m_1 + 1) & \text{if } z_n = 0 \end{cases}$$

Where J is the number of MRGs used in the CMRG, j , n , k and m_j are positive integers, and each $a_{j,k}$ belongs to $Z_{m_j} = \{0, 1, \dots, m_j - 1\}$, δ_j are integers, and the greatest common divisor of δ_j and m_j is one for each j . To have fast algorithms, with a given j most $a_{j,k}$ should be 0. The transformation of u_n makes sure that u_n is never equal to 0 or 1 (otherwise, trouble may arise, e.g., when taking the logarithm to generate an exponential random variate). Assume that the m_j are distinct primes and that each recurrence j has a primitive characteristic polynomial, and thus period length $\rho_j = m_j^k - 1$ and the longest possible period for a CMRG is $\rho_1 \dots \rho_J / 2^{(J-1)}$ (L'Ecuyer, 2013).

The combined generator is a close approximation to a single MRG with a modulus equal to the product of the moduli of the components MRGs. Thus, the CMRG has the advantages associated with a larger modulus while permitting an implementation using smaller values. The CMRG combining multiple recursive sequences provides an efficient way of implementing random-number generators with long periods and good structural properties. If the parameters are well chosen, such generators are statistically far more robust than simple linear congruential generators that fit into a single computer word (L'Ecuyer, 1999).

The Need for Multiple Substreams

Many disjoint random number subsequences are often required in simulation studies, for instance, (1) to make independent replications and/or (2) to associate distinct “streams” of random numbers with different sources of randomness in the system to facilitate synchronization for variance reduction. To produce such “streams,” different seeds (values of vector $\mathbf{S}_i$) must be obtained far enough apart in the sequence to ensure that the streams do not overlap. Selection of seeds should also consider statistical properties between streams, such as apparent independence.

In other words, given any X_i (with seed $\mathbf{S}_i$) and positive integer v , there should be a quick way to compute X_{i+v} (with seed $\mathbf{S}_{i+v}$) without generating all intermediate values. The availability of efficient jump-ahead methods is very useful because it permits one to partition the RNG sequence into long disjoint stream and substreams of random numbers. Most packages offer no facility for jumping ahead directly from X_i to X_{i+v} or to compute distant seeds efficiently. Many simulation languages offer a limited number of streams, all based on the same generator, but using fixed starting seeds set say 100,000 values apart. This provides relatively low flexibility. Suppose, for instance, that you want to perform independent pairs of replications with common random numbers across the configurations (i.e., between any two runs of the same pair) to compare two different configurations of a system.

To insure proper synchronization, you want every generator to start from the same seed in both runs of the same pair. However, in general, these two runs will make a different number of calls to a generator, and programming “tricks” should be used to skip a proper amount of random numbers to resynchronize the generators for the next pair without overlap in the random number streams. This requires extra programming effort and could be error prone. Good software tools should ease the programmer’s task in that respect. A simple procedure call should permit resetting a generator to previous seed or jumping ahead to a new seed for the next run. Of course, the sequence of “new seeds” (one per run) should be the same of both configurations for the system. Implementing such tools requires efficient “jumping ahead” facilities, which in turn ask for efficient procedures to compute $(a \times s \text{ MOD } m)$, where a and s are positive integers. For examples showing the usefulness of substreams, see L’Ecuyer (2015).

Computing $(a \times s \text{ MOD } m)$

Consider a 32-bit computer on which all integers between -2^{32-1} and $2^{32-1} - 1$ are well represented. We want to compute $(a \times s \text{ MOD } m)$, where a , s , and m are positive integers smaller than 2^{32-1} . Without loss of generality, we assume that $a < m$ and $s < m$ (if not, replace a and s by $a \text{ MOD } m$ and $s \text{ MOD } m$, respectively). To keep seeds with 32-bit precision, all operations cannot produce any number greater than 2^{53} (the IEEE-754 standard, i.e., the floating-point numbers have at least 53 bits of precision for the mantissa). Therefore, special algorithm was needed to compute $(a \times s \text{ MOD } m)$, where a and s are less than 2^{32} (around 4.3×10^9).

The following algorithm was used. Let

$$a = a_1 \times 2^{17} + a_2$$

so

$$a \times s = a_1 \times s \times 2^{17} + a_2 \times s$$

Therefore,

$$a \times s \text{ MOD } m = \left((a_1 \times s \text{ MOD } m) \times 2^{17} + a_2 \times s \right) \text{ MOD } m$$

Where $a_1 < 2^{15}$, so $a_1 \times s < 2^{47} (= 2^{15} \times 2^{32})$, and $a_2 < 2^{17}$, so $a_2 \times s < 2^{49} (= 2^{17} \times 2^{32})$. Because $z = (a_1 \times s \text{ MOD } m) < 2^{32}$, we have $z \times 2^{17} < 2^{49}$ so that all the intermediate terms in the above computations are less than 2^{53} . Therefore, all seed values will have exact accuracy.

Note that $(a \times s \text{ MOD } m)$, where a and s are less than 2^{32} , can be computed directly on 64-bit computers that can perform operations with 128-bit quadruple precision, i.e., numbers as large as 2^{113} (around 1.0×10^{34}).

Computing the Jumping Matrices

The initial state of substreams can be computed easily if jumping-ahead facilities are available for the individual MRG components; that is, if an efficient algorithm is available for computing the state of the MRG v steps ahead of the current one, for large values of v . L'Ecuyer (1990) explained one way of doing that, based on the fact that the MRG can be viewed as a LCG in matrix form, whose state is a k -dimensional vector and whose multiplier is a $k \times k$ matrix A . To jump ahead by v values, just multiply the current state by $(A^v \text{ MOD } m)$. The matrix $(A^v \text{ MOD } m)$ can be pre-computed in time $O(\log_2 v)$, using the divide-and-conquer algorithm (Knuth, 1997).

That is, for the MRG random number generator, X_{i+v} can be computed directly from X_i using

$$X_{i+v} = (A^v X_i) \text{ MOD } m = (A^v \text{ MOD } m) X_i \text{ MOD } m$$

where

$$A = \begin{pmatrix} 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\ a_k & a_{k-1} & \cdots & a_1 \end{pmatrix}$$

is an invertible $k \times k$ matrix and

$$X_i = \begin{pmatrix} X_i \\ X_{i+1} \\ \vdots \\ X_{i+k-1} \end{pmatrix}$$

is a $k \times 1$ vector. When A has this special structure, the first $k-1$ components of X_i are obtained by shifting the last $k-1$ components of X_{i-1} , and the last component of X_i is a linear combination of the components of X_{i-1} , according to the MRG (L'Ecuyer, 1990). Kroese et al. (2011) point out that an MRG can be interpreted and implemented as a matrix multiplicative congruential generator, i.e.

$$X_i = (AX_{i-1}) \text{MOD } m, i = 1, 2, \dots$$

The divide-and-conquer algorithm (Knuth, 1997) was used to compute the jumping matrices A^v using the following recursion:

$$A^v \text{MOD } m = \begin{cases} A & \text{if } v = 1; \\ A(A^{v-1} \text{MOD } m) \text{MOD } m & \text{if } v > 1, v \text{ odd}; \\ (A^{v/2} \text{MOD } m)(A^{v/2} \text{MOD } m) \text{MOD } m & \text{if } v > 1, v \text{ even}. \end{cases}$$

A Random Number Package

We now propose a portable set of utilities for random number generation. We consider a basic underlying generator of period p . Let s_0 be the basic seed (initial state) for this generator and $s_1, s_2, \dots$ be its sequence of successive states. Let T denote the transition function of the generator, that is, the operator $T: S \rightarrow S$ such that $T(s_i) = s_{i+1}$, and T^q its q -fold composition ($T^q(s_i) = s_{i+q}$). Starting from states $I_1 = s_0$, $I_2 = s_q = T^q(I_1)$, $I_3 = s_{2q} = T^q(I_2)$, ..., $I_G = s_{(G-1)q} = T^q(I_{G-1})$, respectively. Each of these G sequences correspond to a “stream”, with length q . Note that q needs to be a very large number, say no smaller than 10^9 . Hence, there will be G virtual RNGs. I_g is called the *initial seed* of stream g . At any moment during program execution, stream g is in some state C_g , say, in its subsequence number r , that is, such that $C_g = T^{r-1}(I_g)$. We call C_g the *current state* of stream g .

The product of $a_{ij}(m_j-1)$ is less than 2^{53} . If this condition holds, then the integer $a_{ij}x_{ij}$ is always represented exactly in floating point on a 32-bit computer that supports the IEEE floating-point arithmetic standard, with at least 53 bits of precision for the mantissa. The generator can then be implemented directly in floating-point arithmetic, which is typically faster than an integer arithmetic implementation. On the other hand, with this implementation, the state of the generator is represented over $64k$ bits, as opposed to $32k$ bits when the x_{ij} are represented as 32-bit integers.

The mrg32k3a of L'Ecuyer (1999) implemented a CMRG with 2 components ordered 3, whose coefficients satisfy above condition. The moduli and coefficients are $m_1 = 2^{32} - 209 = 4294967087$, $a_{11} = 0$, $a_{12} = 1403580$, $a_{13} = -810728$, $m_2 = 2^{32} - 22853 = 4294944443$, $a_{21} = 527612$, $a_{22} = 0$, $a_{23} = -1370589$. Its period length is $\rho = (m_1^3 - 1)(m_2^3 - 1) / 2 \approx 2^{191} \approx 3.1 \times 10^{57}$. This implementation set $\delta_1 = -\delta_2 = 1$. The parameters have been chosen so that the period is long, a fast implementation is available, and the generator performs well with respect to the spectral test. The mrg32k3a has been implemented as one of the core random number generators in many simulation packages.

Before this procedure is called for the first time, one must initialize the global variables s_{10}, s_{11}, s_{12} to (exact) non-negative integer values less than m_1 and not all zero, and s_{20}, s_{21}, s_{22} to non-negative

integers less than m_2 and not all zero. The vectors (s10, s11, s12) and (s20, s21, s22) are the initial values of $(x_{1,0}, x_{1,1}, x_{1,2})$ and $(x_{2,0}, x_{2,1}, x_{2,2})$, respectively. They constitute the *seed*.

Therefore, in this implementation

$$x_{1,n} = (1403580.0x_{1,n-2} - 810728.0x_{1,n-3}) \text{MOD} 4294967087$$

$$x_{2,n} = (527612.0x_{2,n-1} - 1370589.0x_{2,n-3}) \text{MOD} 4294944443$$

$$Z_n = (x_{1,n} - x_{2,n}) \text{MOD} 4294967087$$

$$u_n = \begin{cases} z_n / 4294967088 & \text{if } z_n > 0 \\ 4294967087 / 4294967088 & \text{if } z_n = 0 \end{cases}$$

The matrix A_1 for s_{1n} to jump ahead one step is

$$A_1 = \begin{pmatrix} 0.0 & 1.0 & 0.0 \\ 0.0 & 0.0 & 1.0 \\ -810728.0 & 1403580.0 & 0.0 \end{pmatrix}$$

and the matrix A_2 for s_{2n} to jump ahead one step is

$$A_2 = \begin{pmatrix} 0.0 & 1.0 & 0.0 \\ 0.0 & 0.0 & 1.0 \\ -1370589.0 & 0.0 & 527612.0 \end{pmatrix}$$

The following is an implementation of the CMRG (L'Ecuyer's mrg32k3a) in C.

```
#define norm 2.328306549295728e-10 // 1.0/(m1+1)
#define norm2 2.328318825240738e-10 // 1.0/(m2+1)
#define m1 4294967087.0
#define m2 4294944443.0
// the initial seed
double s[2][3] = {
    {0.0, 0.0, 1.0},
    {0.0, 0.0, 1.0}
};
double MRG32k3a()
{
    long k;
    double p;
```

```

p = 1403580.0 * s[0][1] - 810728.0 * s[0][0];
k = long (p / m1); p -= k*m1; if (p < 0.0) p += m1;
s[0][0] = s[0][1]; s[0][1] = s[0][2]; s[0][2] = p;
p = 527612.0 * s[1][2] - 1370589.0 * s[1][0];
k = long (p / m2); p -= k*m2; if (p < 0.0) p += m2;
s[1][0] = s[1][1]; s[1][1] = s[1][2]; s[1][2] = p;
if (s[0][2] <= s[1][2]) return ((s[0][2] - s[1][2] + m1) * norm);
else return ((s[0][2] - s[1][2]) * norm);
}

```

See Chen (2016) for examples on how to use this RNG. The mrg32k3a RNG software packages are available for download via url <http://www.iro.umontreal.ca/~lecuyer/myftp/streams00/>

Jumping Backward

The jump-back matrix also exists. This is true because each component has a primitive characteristic polynomial (a necessary condition). Given a vector s_n , one may jump back v steps to s_{n-v} . For example, the jump-back-one-step matrix B_j is $A_j^{\rho_j-1} \text{ MOD } m_j$, where ρ_j is the period of the j th MRG of the CMRG. As one might expect, $A_j^v \times B_j^v \text{ MOD } m_j$ turns out to be the identity matrix I , for $v=1,2,\dots,\rho_j$. This equation is consistent with our intuition that $A_j^{\rho_j-1} \text{ MOD } m_j = I$, and this follows from Fermat's theorem. The matrix B_j generates the same stream but in reverse order. As we can see from the new recursion below, the values of the parameters b_{ij} are much larger than the original ones, where b_{ij} are the parameters of the new CMRG. Furthermore, we no longer have $b_{ij}(m_j-1) < 2^{53}$ for all b_{ij} . Therefore, the original recursion provides a more efficient generator.

The matrix B_1 for s_{1n} to jump back one step (i.e., jump ahead ρ_1-1 step) is

$$B_1 = \begin{pmatrix} 184888585.0 & 0.0 & 1945170933.0 \\ 1.0 & 0.0 & 0.0 \\ 0.0 & 1.0 & 0.0 \end{pmatrix}$$

and the matrix B_2 for s_{2n} to jump back one step (i.e., jump ahead ρ_2-1 step) is

$$B_2 = \begin{pmatrix} 0.0 & 360363334.0 & 4225571728.0 \\ 1.0 & 0.0 & 1.0 \\ 0.0 & 1.0 & 0.0 \end{pmatrix}$$

The reverse stream follows the recursion

$$x_{1,n} = (184888585.0x_{1,n+1} + 1945170933.0x_{1,n+3}) \text{ MOD } 4294967087$$

$$x_{2,n} = (360363334.0x_{2,n+2} + 4225571728.0x_{2,n+3}) \text{MOD} 4294944443$$

or

$$x_{2,n} = (360363334.0x_{2,n+2} - 69372715x_{2,n+3}) \text{MOD} 4294944443$$

Generating Nonuniform Random Variate

To simulate the underlying system under study, various nonuniform random variates are required. These random variates are used to simulate the observations from the desired distribution. Random variates from distributions other than the uniform $[0,1]$ are generated by applying further transformations to the output value u_i of the uniform RNG. The simplest way of generating a random variate X with distribution function F is using the inverse transformation. Let $U(a,b)$ denote the uniform distribution between a and b . Based on the fact that $y=F(x) \sim U(0,1)$, we generate a random variate $U \sim U(0,1)$ and return the value $X=F^{-1}(U)$ as a variate with distribution F . Here F^{-1} is the inverse distribution function (or quantile function) and is defined by

$$X = F^{-1}(U) = \inf \{x : F(x) \geq U\}.$$

Note that

$$P(X \leq x) = P(F^{-1}(U) \leq x) = P(U \leq F(x)) = F(x).$$

For more information of using inverse transform to generate random variates, see Law (2014). Other methods are available when F^{-1} is difficult or expensive to compute, see Kroese et al. (2011).

FUTURE TRENDS

Random number generators continue to be key components of any computer simulation, cryptography, and other areas where producing an unpredictable result is desirable. As computers become 64-bits based operation, RNGs based on 64-bits will be developed. Utilities for RNGs will be incorporated into many simulation packages and will be readily available for simulation practitioners. Furthermore, newer true random number generators based on hardware devices are continually being developed. These hardware devices are important components of blockchain environment, where cryptography and security are essential.

CONCLUSION

Sequence of pseudorandom numbers is not truly random, because it is completely determined by an initial value, i.e., seed. Although sequences that are truly random can be generated using hardware random

number generators, pseudorandom number generators (based on mathematical algorithm) are important in practice for their speed and their reproducibility. We have discussed the backbone CMRG random number generator, several utilities to enhance its practical use, and implementation issues. Our implementation eliminates the need to use a fixed number of pre-computed seeds, which would provide little flexibility. The proposed random-number-generation package provides jumping facilities, has good speed, a long period length, and excellent theoretical/statistical properties. It provides for multiple generators (streams) running simultaneously, and each generator (stream) has its sequence of numbers partitioned into many long disjoint contiguous substreams. The RNG mrg32k3a has been studied intensively and implemented in several software packages.

KEY TERMS AND DEFINITIONS

Blockchain: A blockchain is a growing list of digital records of transactions, called blocks, which are linked together using cryptograph. Each block contains a cryptographic hash of the previous block, a timestamp and transaction data.

Common Random Numbers: A variance reduction technique that uses the same random number streams to simulation different systems.

Deterministic Algorithm: An algorithm that given the same input always products the same outputs.

Deterministic Sequence: A sequence that the value of any future elements can be determined when the value of the current element is known

Jump Ahead (Back) v Steps: A utility to advance (go back) v steps in the random number stream without going through the stream sequentially.

Period Length (of RNGs): The length of the random number sequence before it recycles itself.

Quantile Function (Inverse Distribution Function): The quantile function (given a probability p) returns the value at or below which $100p$ percent of the population lies.

Random Number Generators (RNGs): Computational or physical devices designed to generate a sequence of numbers that appear to be random, as determined by statistical tests.

Variance Reduction: A technique to reduce the variance of the estimate, hence, increase the precision of the estimate.

Individual Cloud: After Cloud

INTRODUCTION

It is just now at the top of an aggregation point of globalizations' era in terms of things and living creatures. And the communication methods including in many sorts of transfers like commodity, facility, information, system, thought, knowledge, people, culture, heritage, etc. may cause many kinds of and many types of interactions among us, which may have made the world closer but complex, smaller but intense, influential but solitude, networked but dividable, accumulated but distributed, direct but stand-still, stable but chaotic, abstracted but differentiated loosely, many possibilities but almost none, free but controlled, unique but ubiquitous, solitude but mass, directed but diverge, and accumulated knowledge but ordinal. As the results of these situations, they may cause even an individual world much wider or smaller, closer or divided, quicker or slower, dependent or independent, massive or nothing, unique or ubiquitous, far expanded or shrunk, any opportunity expected or nothing desired, viewable or invisible, manageable or uncontrollable, simple or chaotic, and limited or borderless. As it is observed, these phenomenon in the world is being existed as an extreme opposite twin (dipole, pair) unit at the same moment. This has been the causations of the Multi Dipoles. This phenomenon of the Multi Dipoles has caused the situations of many kinds of Mini Clouds by being used of the Information Technology (IT) for offering necessary information to us individually. This phenomenon of the Multi Dipoles seems to be further deepened and extended under this phenomenon. But on the contrary, this phenomenon turns out to be the opposite direction. That is to say, this phenomenon will make the Multi Dipoles converge into Unique Dipole in the very near future as the public usages will go to the two kinds of categories (groups) of people; Simple Users and Controlled Venders.

Talking about the functions of Mini Clouds in the same flow, it will become possible to access seamlessly to any Mini Cloud whose phenomenon will make the Mini Clouds converge into the Unique Cloud. Under these situations and conditions, an individual is able to get a thing and information as many and as much as being wanted in order to accomplish one's desire, which is very easy to do. But on the other hand, it is very true to say that the thing and the information will be offered to anybody as "a unit (a black box)" that it is not possible to go into further details to change, moderate, and manage a concerned matter. This phenomenon will likely lose a thing and information of originated matters silently without being recognized by users as many and as much as users used to have.

And it also can be said that, under these situations and conditions, almost everything in the world may interfere one another randomly, massively, closely, seamlessly, dividedly without being noticed to the users. And what is more, this phenomenon will go on further beyond year by year aggressively. In these chaos like conditions, everything and every matter will be gone further deepened Clouds entities inside, so that nobody will have a chance to recognize what is happening in reality world.

DOI: 10.4018/978-1-7998-3479-3.ch014

So here studies on the problems caused by these situations and conditions. And here will propose a method to resolve some of the problems caused by these situations by an idea of “Individual Cloud”.

BACKGROUND

There are so many kinds of tool, system, software, hardware, knowledge, thought, idea, principle, theory, and various kinds of human behaviors linked with Internetworking by Information Technologies that have been facilitating human actions even in cases at Dense Interference Space (DIS). DIS is a place where so many people or information is gathered randomly unintentionally on a networking or at a physical place. In the Interfering One Another (IOA) at DIS, it will be able to take any actions, for example, manufacturing fine goods, transporting goods, reducing a cost, solving a problem in managing a company, keeping an environment as they should be, making money, getting an information, making a new idea, learning, communicating, knowing, creating, diverging, etc. DIS could be appearing anywhere with any idea at any time purposely or coincidentally as a history tells us in the networked societies. And DIS may have an influential aspect in guiding a social and a technical direction without giving us any intention beforehand. And this tendency could not be stopped by anybody with any idea under the conventional ideas, thoughts, knowledge, and actions even though the tendency would be wanted to avoid.

In the present societies under these situations as mentioned above, there should be bearing various sorts of and many levels of DIS here and there. And some of them are brand new ones with a novel knowledge, and the others are mixed with new knowledge and conventional ones, and the another are with stuck of “obsoledge” (“obsoledge” means “obsolete” + “knowledge” by Toffler, 2010.).

Under this circumstance, any output of a service processing at DIS, for example, will be easily affected goodly or badly by Handling Method Of Knowledge (HMOK), Handling Method Of Knowledge Value (HMOKV), and Intelligence Of Knowledge (IOK) itself, which are closely related with cores of Clouds.

Technically speaking, it is now under “Techno National”, “Techno Hybrid”, and “Techno Global”. Under these situations, industries have been transferring their production spots to abroad from a developed country to reduce a production cost and a labor cost. As result of this, some of technologies of industries in those countries should be fading away and down to nothing (zero), and what is more, a deflation will be going on in those countries. Under these situations and conditions, ordinal machines equipped industries and traditional production methods used industries may have difficult and hard moments for surviving at the places where they used to have situated at. On the other hand, it is not so easy matter to create a new industry or a company in the replaces of the conventional companies as there is not any stable space for any purpose to be achieved easily in reality.

However, at present, in terms of these matter, it could be and can be thought of some of the methods to overcome these problems and the situations for surviving. And they are shown in the followings.

1. To become “Far Advanced Company in Technology and Management”:

This means that a company has the following functions.

- a. A company has a far advanced core technology.
- b. A company has the top share of distinguished goods in a limited field.
- c. A company has the best engineers and technicians in a field.
- d. A company has a unique management strategy and a good turnover.
- e. A company has constantly a new development.
- f. A company has collaboration with Universities.

- g. A company has good concerns with an environment and a natural resource.
 - h. A company may give employees nice motivations for working.
2. **To have “Alliance with Company in Developing Country”:**
This means that a company has a production spot in Asia or in South America in order to reduce a production cost and labor cost.
- a. A company has a distinguished management.
 - b. A company has a strategy of “Goods from Asia or from South America to the world”, for example.
 - c. A company has a unique planning section.
 - d. A company has a multiple management.
3. **To become “Global Company”:**
This means the following thing.
- a. A company will become a global company. That is to say, a company will stay at the best place (in any country) for production and management as multi-nationals.
4. **To become “Environment Concern Type of Company”:**
This means that a company has the core direction in sustainability in all.
- a. A company has the best concerns with the nature, the natural resources, and responsibilities for the goods produced.
5. **To become “Knowledge Accumulated Company”:**
This means the following things.
- a. Whatever we understand about the world, it is very hard to maintain an established position as a company for good. Generally speaking, it is understood that a company has to have an advanced thought comparing with others’. That is to say, it is very closely related with an idea how much knowledge, which is far advanced compared with others’, a company has. In this case, Knowledge is in a technical field and in a management field, which are closely related with Cloud.
6. **To become “Advanced Information Technology Equipped Company”:**
This means the following thing.
- a. A company has the advanced Information Technologies that may replace a human job by using Cloud.
7. **To become “Company with Niche Goods Production”:**
This means the following thing.
- a. A company has goods that might not interest in the major companies.
8. **To become “Company only in Net”: Company in Digital**
This means the following thing.
- a. A company does not have a physical office at all but it has all the necessary actions in Networking. This is a unique case of using Cloud as Knowledge.
9. **To become “Non Profit Organization (NPO)”:**
This means the following thing.
- a. An organization does not have a targeted making money motivation but has a loosely environment interfered action orientation with a nature, people, economy, culture, education, and the earth. This will be able to become a global but in the sense of economy mono pole.

Whichever the case to face to adopt, all these matters of 1 to 9 are closely related with “Cloud” for the necessary usages in planning, production, management, marketing, service, and sales.

PRESENT PHENOMENON IN SOCIETY AND PROBLEMS FACING

By taking an idea from 1 to 9 described in the previous chapter, a company may have any direction of the methods in order to keep its position in the world and in order to overcome the problems facing for being survived or for getting a higher position with shares and sales. However generally speaking, it is very true to say that the economic situation in the world is not vivid like many decades ago. What is worse, the consumers do not have much intention to buy goods and foods, etc. comparing with the decades ago. Because almost everything can be got in the world when it is desired through Networking, for example. They can be easily transported even if they are away from us in distance. They also can be simply transferred through a computer networking if they are data, images, and information technology related matters. They are able to come upon to us by the transfers without any information contained just as a matter of “THING”, which means that Goods has been arrived upon us just as a final matter of “THING” without making us known its Contents, Relations, and Meanings.

If it will be allowed to describe the above phenomenon with a bit of over expression, they may have lost these Contents, Relations, and Meanings of Goods and Foods before they have been delivered to us. And it is quite natural and easy to lose the values of them too at the time when they are used or are eaten. As the result of this, it is quite natural that the interests on Goods or Foods might be lost too although the producers and raisers have been doing much effort on adding the values onto them.

In another word, if it will be concluded to say, the world will be surrounded by full of simple matters of “THING”, which might make us easily loose interests on Goods and Foods. And ultimately, the world will be surrounded by “simply a function” and “simply a matter” by “THING” that have been asked to possess. As the result of this, a consumer will be fed up with them sooner or later by “a function” and “a simple matter”. And a new Goods or Foods will be asked for soon after by a consumer. And in this vicious circle, it might be said that a deflation will be on, which will make an economic basic ground become smaller and smaller and will be likely shrunk to zero without any notice to us.

So, in short, what are the problems under this phenomenon in the case of production, market, and sales? They will be the followings.

1. A consumer will easily loose an interest in Goods, etc. sooner or later, and so the values that are existed on Goods, etc. will be fading away to nothing suddenly and instantly. As the result of this, a market size will have a tendency to diminish itself suddenly and instantly.
2. DIS will come up to the world suddenly and without any notice. So a new market will have a tendency to come up to the world suddenly without any notice to us.
3. Tendency is not a matter that is able to control easily.
4. A value is not a matter that is able to create easily.
5. Consumers are independent nowadays, and so they are independently taking any thought and action in all over the world. As the result of this, to grasp and to know a mass behavior is not an easy matter.
6. Data processing methods are in full for use today but it is hard to use them properly. It is asked to have a method to use them simply, intentionally, knowledgably, and intelligently. This situation is really the matter of “Cloud” to come up and to use.

KEY FACTOR IN THE PROBLEMS SOLVING

In the previous chapter, the problems facing are extracted and are discussed. And here they will be studied further in order to find the core matter to cause the problems if there is any.

It will not take much time to find the core matter of the problems studied in the above chapter when it is thought out.

A new product has been asked almost every instance in commodities, in hobbies, and in lives. Or in another expression, a company has been offering a new product at every instance. This phenomenon shows that values, meanings, and relations of them have been lost sooner or later, which were existed on them. But what happens if those things likely loose values, meanings, and relations of them in much longer time. In another word, if much important and vivid information are kept on a certain goods, they will be kept for them until the mechanical functions are damaged for use. In another word, “Contents (C)”, “Relations (R)”, and “Meanings (M)” of Goods, for example, are the core matters (the core factors) for us to keep our interests on Goods. It also can be concluded by looking back of this phenomenon that those core matters (C, R, and M) should be strongly combined with “an intention to buy”.

It is obviously to say that the following two subjects of 1 and 2 are important actions and functions if there is a sale of Goods on a market;

1. Goods should have good reasons of “Contents”, “Relations”, and “Meanings” that belong to its own.
2. “Contents”, “Relations”, and “Meanings” should be within a quite understandable situation for anybody. And so, those things should be seen or taken or used quite easily by “anybody” at “any time” when those are wanted to.

Today, there are the following systems and functions in order to produce Goods in a costless and in a labor redundant manner as a broad sense of a management field.

SAP; (Enterprise Resource Planning)

SOA; Service Oriented Architecture

SaaS; Software as a Service

Mash Up; Mashing Up software

Meta Frame; (peer to peer relation)

PaaS; Platform as a Service

HaaS; Hardware as a Service

IaaS; Infrastructure as a Service

Cloud; Cloud Computing within a particular area

Mini Clouds; Various Kinds of Small Cloud

Those systems and functions mentioned above have been concluded as a part of “Cloud” computing in order to solve any kind of problem.

But nowadays there is the fact that it is not possible to invest so much money on a company system for solving the problems. Because skilled and educated engineers might be offered in the areas of developing countries, and those won’t cost so much comparing to the systems mentioned above. And they may be creative which cannot be done by the computer systems mentioned above. So the companies try to use those engineers instead of using a high cost of the computer systems with SAP, SOA, SaaS, PaaS,

HaaS, IaaS, Cloud, etc. And what is more, it is quite hard to create and add the two subjects mentioned above on Goods, for example, by using the above computer systems and the functions instantly.

CLOUD ORIENTED SERVICE IN SERVICE SCIENCE

Here introduces a new idea of “CLOUD ORIENTED SERVICE IN SERVICE SCIENCE” by using the method of “Accumulation and Integration in Seamless Knowledge”, which will be able to solve those problems mentioned in a sense of “Service” with a low labor cost and a low production cost.

DEFINITION OF CLOUD ORIENTED SERVICE BY BEHAVIOR

“By entering into the “CLOUD ORIENTED SERVICE” system, the desire (subject, problem) will be solved and offered by means of SERVICE; BPOSS, POSS, BFOSS, BSOSS, and IMOS. And this SERVICE consists of Field Analysis, Categorical Analysis, Functional Analysis, and Knowledge Enhancement in the mixed ways. And the services will be mainly offered by the computer systems, which may need some simple data-input.”

In this manner, Service as Field Analysis will be firstly defined with five service systems as described below.

Service

Service Field

1. Business Plan Oriented Service (BPOS):

Generally speaking, there are so many businesses in this world and also there will come up new businesses to the world day by day. It is true to say that each business itself is slightly different from one another in a sense of goods, a shape, a production method, a market, a customer, an environment, etc. But they may be divided as field (gathered as a bundle of groups) by a system structure, a kind of goods, a process kind, a market kind, etc., which should make the number of the businesses' fields small in quantity. That is to say, it will be possible to have a business plan for each field as “A Generalized System of Service” (Business Plan Oriented Service System: BPOS), which will be able to offer the following Service.

- a. BPOS can make use of database for a new generalized business plan (Contents).
- b. BPOS is able to offer one of the business plans for planning and controlling, or for getting assistance out of BPOS in managing.
- c. BPOS may make use of the database for using other purposes (Relations) by connecting to other systems with IT facilities like Printer, CAD/CAM, etc.

2. Project Oriented Service (POS):

Now it is a common thing that we have some projects derived from a public sector (government, or NPO, etc.), a private sector, and an Academy Sector. These are Project Oriented Service (a theme of a project purpose is defined), which means that these are usually processed by collaboration among Private

Sector, Academy Sector, and Public Sector. That is to say, each sector should be responsible for some parts in the project in order to get a purpose accomplished. In this case, the things that are needed will be decided before starting a project. So the services offered for projects will be the followings.

- a. POS can manage the whole project and can do “Check – Plan – Do – Evaluation - Action” circle. And this can offer and create Meanings.
 - b. POS has flexibility for adding and reducing a process of the system targeted.
 - c. POS may have a human interaction (of a coordinator) from time to time. In this case, a purpose of a project will be clearly decided before the start but not for methods to get the output.
3. Business Fostering Oriented Service (BFOS):

When a business plan starts, it is a usual thing to say that there might be a problem for processing at some part during the operation. This kind of problem should be sort out by as soon as possible. For doing this kind of problem solving, it is very useful to have a similar kind of process example, which will give and offer a solution tips for the problem facing. So the services offered will be the followings. After having gone through this process, a new knowledge will be created, or value added knowledge will be made on.

- a. BFOS can offer necessary information (Contents, Relations, and Meanings) including a method from the database accumulated from day by day processing when the business has a problem.
 - b. BFOS can offer a new-targeted mass (Relations) for sales, a new strategy for processing, and a new category for promotion, etc. by using an information retrieval system and GPS system.
 - c. BFOS can offer a market research activity (Relations) by using the several analysis methods offered by the BFOS.
4. Business Skill Oriented Service (BSOS):

There are many skills and tactics in a field of business when a business is under operation. And these skills will be usually stored in a computer system as a knowledge base in order to use them for future. And an old knowledge will be transformed into a new knowledge through this process.

- a. BSOS can offer business skills and tactics (Relations).
 - b. BSOS can store the skills and the tactics by the system in Database.
5. Information Management Oriented Service (IMOS): (Suzuki 2013)

It always happens to get new information, and to process it, and to accumulate it by adding other related information. And those of many kinds of accumulated information need to be managed in the way to facilitate a problem solving and desired structure formation in processing.

- a. IMOS can offer a problem solving technique by using various kinds of information on one computer screen. And those kinds of information can be searched, accumulated, processed, and added onto a system as a new knowledge by using Web., Google, and Data stored.
- b. IMOS can offer the publication processes in any stage. And also this can offer an increment in knowledge enhancement.

Here explains about the system behavior of “CLOUD ORIENTED SERVICE” system.

The system consists of the four categories (BPOS, POS, BFOS, BSOS, IMOS) as mentioned above. The processes for Service Action as Categorical Analysis will be explained in the following subsection.

Service Action:Sugiyama, Suzuki (2012)

1. Enter with “Subject”

Go to the system with “a subject”. And go further into **BPOS**, which will offer a related category with the subject. And find the categories related with the subject.

2. Get Subject Required

Find the category related with the subject that will offer a desired output.

3. Processing with Service

After having found the related category, it will start processing for inputting the subject in order to get a desired output.

4. Evaluate Output

It is very important to know whether the output offered is valuable/acceptable or not. If the output is all right for use, this will be terminated.

5. Goto First Stage

If the output is not valuable for use, go to the “first stage of the system” to find more appropriate category.

The processes for Service Improvement as Functional Analysis will be explained in the following subsection.

Service Improvement

1. Get Unsolved Subject

Get an unsolved subject.

2. Resolve It with Services

Find the related functions for the subject by using the related categories. And then by using the categories, find out relatively influenced functions by the subject. If there are adding factors and functions, manipulate them by using this system. And then store it as a generalized system for service.

3. Evaluate It with Output

Find out the output whether it is good for use or not. It is good for use, and then stores it as one of the services onto Service Category with the functions used.

4. Store It as Service

If the output is not valuable for use, go to the “first stage of the system”.

The General System Behavior

By using the method studied in the above sub chapters, we can create “**CLOUD ORIENTED SERVICE**” system of which the general system behavior is described below.

The system INPUT is for the desire at the place for “Service with Subject in a certain field”, and then the desire will be categorized according to the content (elements) of the desire. And then the process center will be transferred to “Mini Cloud” of which is the most suitable for the desire. And then “Mini Cloud” will be getting an appropriate answer by interchanging the information with “**CLOUD ORIENTED SERVICE**”. And then, the general behavior of this system will give us a notice what sort of service field and category that we are interested. By then, necessary functions will be ready for processing. By telling the category which we need to system, the system lures us one of Mini Cloud, which will give us an answer as OUTPUT.

However, there should be one more thing to think about regarding this matter. That is to say, “Whether or not that there is any limitation in Cloud?” Or “Mini Cloud is good enough for use ?”.

In the next chapter, the limitation will be considered by using a mini Cloud.

SIMPLE EXAMPLE; GSHOP AND INFORMATION MANAGEMENT ORIENTED SYSTEM

Gshop Structure in Field, Category, and Function

Here shows a simple example for making the Mini Cloud system by using Gshop in order to show limitation if there is any.

The whole system consists of the major five subsystems.

1. “Process Template” is to show the present processing contents and the processing results.
2. “ScriptEngine” is for various kinds of Data processing, like “print, mail, SNS, etc.”, “Search and Recommend by using GIS”, “various analysis”, etc.
3. “Database” is for Information, Object, and Person.
- 4 “Various Field Definitions”
 5. “Project Plans and related”

The system behavior for the processing will be shown below.

1. First Stage of the processing:

From “Analysis Threshold”, the system understands which field this subject is related with by using the “Evaluations”. And the system will find that this subject is related with “Project B” mostly. And at the same time, the system knows that “Project B” consists of “Processes A to E”. Each “Process” will get Data from “ScriptEngine” one by one. And the system will give necessary outputs.

2. Second Stage of the processing:

If the outputs are not as suitable as expected, then change the parameters on Process A and Process D. And get the outputs. If the results were good enough to proceed in the real world, then this system ceases to close.

3. Third Stage of the processing:

If the outputs are not as suitable as expected, then change the Processes Methods to Process E and etc. provided. And get the outputs. If the results were good enough to proceed in the real world, then this system ceases to close.

4. Fourth Stage of the processing:

If the outputs are not as suitable as expected, then try to search a new processing method by using a networking, from books, and with computer systems. And this processing will be able to add a new knowledge onto this system as shown in Figure (2) Seamless Knowledge in Gshop. The Knowledge in this processing is to add a new technical processing, a new data processing, a new manipulation, a new thought, a new behavior, a new transformation, and a new relation.

That is to say, this is a processing route to find a new knowledge/rule by abstracting the methods used here repeatedly.

5. Fifth Stage of the processing:

The information and the knowledge that will be accumulated in the Fourth Stage will be able to be enhanced, comprehended, inferred, and enhanced in order to fulfill the information and the knowledge.

These processes from 1 to 5 will be repeated endlessly until one is able to get the output satisfied.

By this method in the seamless knowledge creation processes, one can create a new project which will give a new plan with a new knowledge.

However, it is easy to see that it is very hard to moderate the output after the processes have been completed.

Information Management Oriented System (IMOS): Suzuki (2013)

Here shows a simple example for making Mini Cloud system by using Information Management Oriented System that there is any limitation for use.

This system consists of the following structures.

1. Subject (category);

Each subject consists of project. And each project consists of Contents, Categories, and Objects. Each one of them (Contents, Categories, and Objects) has a seamless relation in the project. So a project is able to be directed onto a certain purpose in order to accomplish a desire by accumulating, enhancing, managing, restructuring, and concluding.

2. Process (Link and Database)

Each process consists of Link and Database. Link and Database have related data, searching data by related data, enhanced knowledge, related data (document, Web, geographical data, XML data, etc.) And each process has a seamless relation in the process.

Through these processes, it is possible to make and enhance “knowledge” in **Mini Cloud**.

However, Mini Cloud may behave only in a limited space which has been created by the above process. This intelligence of Mini Cloud goes under “static behavior” and “closed space (not open for public)”.

AFTER CLOUD

From the above chapters, it is quite natural to see the following things.

1. Things and living creatures are transformed into “a digital world”.
2. The digital world consists of a world of “data”.
3. It might be said that the digital world is “a virtual world”.
4. The virtual world is “a simulation world”, which is not real.
5. “A hypothetical world” mostly leads to the simulation world.
6. It might be said that Cloud goes under the hypothetical world.

If Clouds are “static” and “closed” for users, the output given by Clouds will be the rigid ones. And so, they are all from the virtual world that Cloud has made them by itself. Under this circumstance, the space that the world is facing is absolutely a virtual world. The space must not be cared about whether or not the world is real or not.

There are many kinds of and many types of Mini Clouds in the world. They are individually existed for a targeted customer. But Mini Cloud is Mini Cloud that is able to foster in a very limited category or within a closed area. And it can be said that users have to use many kinds of and many types of Mini Clouds in order to accomplish ones desires. In another word, it has come to the time which all Mini Cloud in the world may act as “knowledge of the world” uniquely. At this time, it will be necessary to access each related Mini Cloud in order to construct “each own knowledge for use”. This is able to be done by the idea of Dynamic Knowledge Wisdom (Sugiyama 2013).

This behaves like “knowledge enhancement cloud” by Net Surfing with the data taken by the structure of groups of URL and groups of Mini Clouds with processing and restructuring.

Dynamic Knowledge Wisdom is a kind of “Smart Cloud (SC)”, which will get and accumulate necessary information by Net Surfing on Webs (Mini Clouds) one after another. SC is formed as series of Mini Clouds (MC), those related data, and those related knowledge as described below.

SC = [MC, Data, Knowledge, Hypothetical World| MC1, MC2, ..., MCn, Data, Knowledge 1, Knowledge 2, ..., Knowledge n, Simulation World 1, ..., Simulation World n]

Inside of Cloud content is searched basically by Behavior of State Comprehension and State Inference, which might be an extension of Eigen Vector and Eigen Value behaviors. And this Mini Cloud (MC) under these conditions is called “Individual Cloud”.

CONCLUSION

Here argued about the following things.

The present real world is equal to the digital world offered by group of Mini Clouds. The digital world is equal to the virtual world offered by Clouds. The virtual world is equal to the hypothetical world that will be made by knowledge computer and the humans. And the hypothetical world is equal to a kind of Cloud.

So those can be expressed as follows.

“The Present Real World” = “The Digital World” = “The Virtual World” = “The Hypothetical World by Simulation” = “Clouds; Mini Cloud, Unique Cloud, Smart Cloud”.

And the hypothetical world is able to be manipulated by a brand new method of “Accumulation and Integration in Seamless Knowledge” by using the knowledge processing mechanisms of “CLOUD ORIENTED SERVICE”, so called Smart Cloud, within a principle of Service Science.

And the following results have been given.

- a. It is shown that “SUBJECT in demand and need” will be resolved by means of the idea of “CLOUD ORIENTED SERVICE; BPOS, POS, BFOS, BSOS, and IMOS in a sense of “Service Science” with the knowledge processing mechanisms of “Accumulation and Integration in Seamless Knowledge”.
- b. By using this method, it will be quite possible to transform “Obsoledge” into “Brand New Knowledge”.
- c. HMOK, HMOKV, and IOK are able to be done by using this method.
- d. It is obvious that this method can contribute to “Cost Reduction and Labor Savings”.
- e. This method can offer any type of fostering to an individual by accumulating and integrating knowledge seamlessly that is likely creating a brand new knowledge.
- f. By using this method, an individual is able to do anything by oneself from the first stage to the final stage for a desire accomplishment assisted by Gshop.
- g. As a next phenomenon in Clouds, an idea of Dynamic Knowledge Wisdom as Smart Cloud is introduced as “Individual Cloud”.
- h. Individual Cloud will have an ability and knowledge to escape from the hypothetical world.

FUTURE WORK AND DIRECTIONS

It will be thought for sure that any kinds of knowledge will be accumulated and enhanced as Unique Cloud and Smart Cloud. And as a result of this phenomenon, the related space for the world will be able to be indulged in the world of getting processed information as a final use of data for a daily life. This is a very comfortable world to live, but, on the other hand, there might be a possibility which there will be many or some who live only under the offered information and knowledge from intelligent computer systems (Mini Cloud, Unique Cloud, Smart Cloud).

So, it is very important to have knowledge of us in investigating whether or not Unique Cloud and Individual Cloud are useful enough to use by inspecting from the outside world even though we are to live in the hypothetical world. Or, in another words, whether or not an individual wants to live in its own individual hypothetical world, or an individual wants to live in another's hypothetical world?

INTRODUCTION

Cloud computing is gaining dominance over the last few years along with its various features such as, on-demand ease of access of computing resources as well as software services. Computing facilities are designed and utilized as a service using virtualization techniques and used as automated business logic in both public and private sectors. Along with various benefits data privacy, data confidentiality and trust establishment are considered to be the main security concerns for an organization to move its data to the cloud platform (Xu et al., 2015; Elfirdoussi, Jarir & Quafafou, 2012). The hasty developments of cloud computing means that cloud services have become the main computing mode on the Internet. Numerous services are offered over cloud to offer analogous functionalities. Despite the fact, the difficulty in identifying trustworthy services has fascinated the attention of researchers (Xu et al., 2015; Elfirdoussi, Jarir & Quafafou, 2012). For this reason, the concepts of trust and reputation had been brought to assess the reliability of cloud services (Li, Zhou, & Yang, 2012).

Reputation is a prejudiced assessment of a cloud service based on personal experience of individual or the advocacy of other users. In recent times, a variety of reputation systems have been proposed to deal with the challenges posed by open and dynamic cloud service environments (Itani, Ghali, Kayssi, & Chehab, 2014). The focus of majority of these systems is on computation of reputation ratings, reputation management, experience, and other features of dynamic environments and provides an appropriate solution to users (Malik & Bouguettaya, 2009; Rathore & Suman, 2013a, 2013b, 2013c, 2016; Yuan, An, & Wang, 2009; Trang, Zhao, & Yang, 2010). However, the survival of biased ratings affects the accuracy of trust evaluations to a great extent. At present, the focus of these reputation models are mainly on the accuracy of trust evaluations (Wang, Zheng, Sun, Zou, & Yang, 2011; Malik & Bouguettaya, 2009a, 2009b); however, these existing methods are limited by personality preference.

At present, to deal with the issue of trustworthiness, computation of the reputation is one of popular method (Elfirdoussi, Jarir & Quafafou, 2012). Reputation is the subject of a lot of interdisciplinary research and can be defined as “the collected and processed information about an individuals’ behavior as observed by others” (Wang, Chao, Lo, Lin, & Wang, 2011). The user can trust the service to a certain extent, based on aggregated feedback given by earlier consumers can be considered as the reputation score of a cloud service. A common attribute in existing cloud computing models is that a universal reputation score is designed through these reputation systems and the value is the same for all consumers. It is commonly used in profit-making location, such as eBay’s feedback mechanism or Epinions (Li, &

DOI: 10.4018/978-1-7998-3479-3.ch015

Wang, 2011). However, in general the reputation is potentially subjective. Feedback ratings are based on the individual's usage experience of a cloud service, which always needs to be seen in the context of the users experience and expectations of a service.

Consider for example two cloud service consumers A (denoted as CA) and B (denoted as CB). They are both looking for a cloud storage service. An industry expert has extremely precise requirements for confidentiality. CB is an amateur whose main aim is to obtain cheap storage. Now consider CB a free storage service is expected to be extremely glad as the cost is minimal and if usability is ok he/she will rank this service very highly. CA might read the small print regarding data policies and is likely to find issues that are not to her liking; so they would rank the service somewhat lower. Of course both are correct in their individual rankings. A global reputation score would not reflect the service users accurately.

Recently, extensive research work has been carried out on reputation prediction of cloud service in which Collaborative Filtering (CF) is extensively used (Xu et al., 2015; Wang, Chao, Lo, Lin, & Wang, 2011; Itani, Ghali, Kayssi, & Chehab, 2014). The classic procedure of CF is firstly to recognize a identical users set or services with identical ratings based on Pearson Correlation Coefficient (PCC), and secondly to use the similar users ratings and/or services to make predictions. Historical feedback ratings contributed by different cloud users are the basis for this prediction. Therefore, the prediction accuracy of CF approaches is highly influenced by the trustworthiness of the user-contributed feedback ratings. However, the present CF approaches uses a theory that all consumers-contributed feedback ratings are trustworthy (Xu et al., 2015; Wang, Chao, Lo, Lin, & Wang, 2011). However, a few feedback ratings can be unreliable due to certain reasons in reality: 1) some users may always give the maximal/ minimal values for the services, (2) cloud service consumers who may be at the same time cloud service providers, intentionally give higher feedback ratings to their own services and terrible mouthing to others services. Therefore, it is significant to consider data credibility to enable more robust service QoS value prediction.

Most existing reputation computation approaches compute service reputation based on QoS parameter and service level. These approaches have a high degree of dependency on the service user's feedback ratings services (Li, Zhou, & Yang, 2012; Li, & Wang, 2011; Trang, Zhao, & Yang, 2010; Malik & Bouguettaya, 2009a, 2009b; Wang, Zheng, Sun, Zou, & Yang, 2011). Assessment of service reputation at QoS parameter level requires that each QoS parameter should be monitored and tracked dynamically because QoS may change over time. Reputation assessment at service level based on a user's feedback rating also bears many problems, such as bias towards positive feedback ratings (Malik & Bouguettaya, 2009a, 2009b). Another problem with user's feedback rating is to ensure its accuracy and trustworthiness that users provide without even knowing much about the service (Wang, Zheng, Sun, Zou, & Yang, 2011; Le-Hung, & Aberer, 2009).

In order to address aforesaid weaknesses, a collaborative ranking approach along with a cloud service reputation model is proposed in this book chapter for detecting the malicious users' feedback rating and evaluating the service reputation. The proposed approach computes the service reputation to discover and select best services over cloud with the combination of user's rating and access rate (Yuan, An, & Wang, 2009; Rathore & Suman, 2013a, 2013b, 2013c, 2016). The former is dependent on user's feedback which is reported after the invocation of services. The later is the access rate, which is obtained through active monitoring of every service to be invoked by service consumer. Malevolent feedback rating using similarity computations are detected by presented approach and reduces the effect of user feedback preferences by Pearson correlation coefficient. An algorithm is also presented for the proposed approach. Wide-ranging experimental result shows that the presented approach can be helpful in improving the reliability of cloud services to be discovered.

This book chapter is organized as follows. Necessary background details related with cloud service reputation is discussed in Section 2. Section 3 highlights the focus of the book chapter along with proposed solution. The proposed collaborative ranking approach along with cloud service reputation evaluation model is presented in Section 4. Section 5 shows the experimental analysis and results of proposed approach. Section 6 discusses the proposed work with its pros and cons and also provides the future research directions. Finally, Section 7 concludes the paper along with the future work.

BACKGROUND

The primary issue among the online as well as offline business communities has always been a reputation. The cloud service consumers choose cloud services based on their reputation. Reputation is a word that has diverse meanings in various domains. It is defined as a needle of whether a user is ready to select a service based on the evaluations of other users. Thus, the result of a reputation evaluation will affect the decision about whether to interact with a service provider. Feedback related to previous interactions among cloud service users and service providers are composed by a reputation system to predict its future reliability (Li, Zhou, & Yang, 2012). Several research works have been carried out on trust and reputation using various mechanisms, such as incentive based, association based, previous invocation based etc.

Selection and discovery of cloud services for individual task is performed with the help of a variety of Quality of Service (QoS) criteria such as reputation, access rate, etc. Cloud service reputation represents a general opinion about its goodness that has been rated based on its various features. It is a communal user's feedback rating who have interacted with or used the cloud service earlier. Feedback rating is the observation of each user about services that has been invoked by them. It could be a sole value in lieu of an overall opinion or a vector representing a value for each QoS parameter of a service, such as response time, reliability and availability. A framework for trust management is introduced to distinguish reputation for various user groups (Xu et al., 2015). One possible solution to achieve is to compute the similarity of consumers rating based on a decision-tree model which clusters feedback into localized scores. A time decay feature appropriate for feedback is also to be considered to refine the result.

Wide-ranging of research work has been carried out on prediction of cloud service reputation, such as collaborative filtering (CF), referral chain, contribution based and previous QoS historical records (Li, Zhou, & Yang, 2012; Li, & Wang, 2011; Itani, Ghali, Kayssi, & Chehab, 2014; Wang, Chao, Lo, Lin, & Wang, 2011). Trust and reputation of a cloud service from consumer's point of view can be the prediction about its future behaviour based on different consumer's rating over its transaction history. Service reputation over cloud can be computed at the level of QoS parameter and service using consumer's rating. Service reputation over cloud based on QoS parameter becomes increasingly challenging when complex and mission critical applications are built upon using cloud services with diverse QoS parameters (Malik & Bouguettaya, 2009). A few QoS parameters, namely, response time changes dynamically; thereby, describing QoS of services accurately becomes complicated. A popularity based service search method is adopted, which consists of tracking all kind of services. Significant information related to discovered, invoked or published services is maintained into database to find frequency of used cloud services, their availability, usage history etc (Li, Zhou, & Yang, 2012).

A reputation as a service system is developed, in which the calculation of the reputation is no longer depending on personal experience but rather on the real-time interaction from the cloud itself (Itani, Ghali, Kayssi, & Chehab, 2014). Malicious feedback detection based on cumulative sum control charts is proposed which reduces the effect of the subjective feedback. A bootstrapping model for reputation

prediction is introduced that assigns reputation to newly deployed services in the absence of their historical information (Rathore & Suman, 2013a; 2013b; 2013c). It introduces the concept of community in bootstrapping in which cloud services related to a specific area of interest are grouped together. Cloud services of specific domain may assist each other in assigning the initial reputation of a newcomer. It uses two reputation bootstrapping approaches; namely, super-peer topology and peer to peer manner. A cumulative sum technique to identify malicious user's ratings is used and it also uses person correlation coefficient to improve the accuracy of ratings (Le-Hung, & Aberer, 2009). A trust reputation architecture is presented for the cloud computing environment to assist the decision making processes of cloud computing customers (Bilecki, L. F., & Fiorese, A., 2017). The reputed trust is based on two trust indicators: objective and subjective ones. The objective trust indicator is based on the historical QoS indicators of a cloud provider. Then, the subjective trust indicator is composed of the users' feedbacks to the cloud providers. Their future work is to apply the presented architecture in a real scenario, through a platform that offers the reputation, and analyze other aspects related to the architecture's performance, such as availability of platform, accuracy of reputation results, nodes reallocation, and analysis of other attack types.

A framework to assist reputation based discovery and matchmaking of cloud services using semantic cloud technologies is proposed (Trang, Zhao, & Yang, 2010). It consists of a communication manager, a matchmaker, a composer, and a reputation manager. In this framework, reputation manager computes the service reputation based on users' feedback and returns the service with highest reputation score based on the user's requirements. Trust and reputation model that uses Bayesian network for cloud services is presented to combine diverse sources, i.e., user's rating, QoS monitoring and direct experience opinion of the requester (Malik & Bouguettaya, 2009). It computes rater's credibility and works well even if some users are malicious. Based on historical user evaluations and their preferences related to specific requirements, a method that revises the reputation rating is proposed (Qingtao et al., 2014). Combining the prior knowledge with a filtering algorithm based on the similarities of evaluations is able to distinguish between unfair ratings in useful manner. This algorithm also includes a market mechanism that allows users and services to act as buyers and sellers. Their method uses only the user feedback ratings data related to a service.

An approach is proposed to compute cloud service reputation according to QoS history and user preferences over QoS attributes (Wang et al., 2011). The quality of rating depends on user's credibility; therefore it uses several techniques to accurately assess it. A method is stated for dynamic computation of reputation of cloud services based on their association among themselves (Elfirdoussi, Jarir, & Quafafou, 2012). The association between any two cloud services is computed based on how often they are composed together. This approach eliminates the dependency on user's feedback, but consists of overhead to maintain the dynamics of the composition and the association coefficient among cloud services. A contribution-based method is presented for propagating reputation from a composite service to its constituent services (Nepal, Malik, & Bouguettaya, 2009). Predefined weights are assigned to component services at the start of composition process. A Novel Active Cloud Service Recommendation (AWSR) approach is proposed which is based on both user's interests and preferences according to usage history to recommend cloud services actively to users (Kang, Liu, Tang, Liu, Cao, & Xu, 2012). An incentive based model is proposed that deals with reputation assessment for cloud service communities (Khosravi-far, Bentahar, Thiran, Moazin, & Guiot, 2009). A Reputation Aware QoS Prediction (RAP) approach of cloud services is presented to addresses the data credibility problem (Qiu, Zheng, Wang, Yang, & Lyu, 2013). RAP firstly calculates QoS values based user reputation contributed by service users' and then selects trustworthy values according to user reputation for prediction.

A reputation based algorithm is presented for evaluating trust which considers the feedback from the cloud service users, queue load and rejection rates of the server in detail (Challagidad, P., Reshmi, V. S., & Birje, M., 2017). Experimental results show that the presented algorithm is efficient for building trust between customers and service providers. Trust reputation architecture is presented for the cloud computing environment in order to assist the decision making processes of cloud computing consumers (Bilecki, L.F., & Fiorese, A., 2017). The presented architecture is responsible to generate aggregated reputation value, provide a module that realizes the QoS indicators monitoring, receive feedback from cloud users to providers in order to update the cloud provider's reputation and assist the decision-making processes in the cloud environment. Their future work is to apply this architecture in a real scenario, through a platform that offers the reputation. It also analyze other aspects related to the architecture's performance, such as availability of platform, accuracy of reputation results, nodes reallocation, and analysis of other attack types. A novel techniques is presented which help in detecting reputation based attacks and allowing users to effectively identify trustworthy cloud services to protect cloud services against their malevolent users and Guaranteeing the availability of the trust management service (Noor, T. H., Yao, L., Sheng, Q. Z., Anne, H.H., & Dustdar, S., 2016). Their future work plans to combine different trust management techniques such as reputation and recommendation to increase the trust results accuracy. Performance optimization of the trust management service is another focus of our future research work.

FOCUS OF THE CHAPTER

However, the trouble of trusting cloud computing is a uppermost anxiety for most organizations in such a way that trust is widely regarded as one of the top obstacles for the adoption and growth of cloud computing. Therefore, there is a need of a trust model which assists cloud consumers to find the provider that best satisfies their trust concerns in cloud computing by measuring the reliability of Cloud Service Provider (CSP). There are a variety of research work presented by existing researchers to assess and predict the service reputation in order to improve the accuracy of reputation result (Bilecki, L.F., & Fiorese, A., 2017; Noor, T. H et al., 2016; Wu, Qingtao et al., 2014; Qiu, Zheng, Wang, Yang, & Lyu, 2013). Their research mainly focuses on two challenges; firstly, computation of cloud service reputation at QoS parameter level requires that each QoS parameters should be monitored and tracked dynamically due to its dynamic nature. Secondly, dependency on cloud service user's feedback has some practical constraints, such as, complicated to guarantee the accuracy and reliability of user's feedback due to different abilities and intentions of users. Thirdly, difficult to evaluate service reputation in absence of user's feedback (Wang et al., 2011; Qiu, Zheng, Wang, Yang, & Lyu, 2013; Noor, T. H. et al., 2016; Bilecki, L.F., & Fiorese, A., 2017). In this book chapter, we have also dealt with said challenges and propose a collaborative ranking approach along with a cloud service reputation evaluation model which assesses the service reputation by collecting and combining the reputation data from multiple sources, such as access rate (Rathore & Suman, 2011, 2013, 2016, 2017) and user's rating to improve reputation result accuracy. This combination aims at reducing the probable unfairness of user ratings and helpful in improving the trustworthiness in predicting service reputation in cloud environment. Extensive experiments showed that proposed method distinguished and filtered unfair ratings correctly, while it could also recommend appropriate services for a specific user based on their preferences in a dynamic market environment.

PROPOSED COLLABORATIVE RANKING APPROACH

Improved trustworthiness of cloud service reputation does not necessarily ensured by relying on the cloud service user's feedback completely. Numerous papers have illustrated the need to use various sources of evidence due to the inherent unreliability of user feedback (Khosravifar et al., 2009; Wang, Sun, Zou, & Yang, 2011). Reliability in prediction of service reputation can be obtained by considering one more opinion about service reputation and combine it with the reputation obtained through user's feedback ratings. In other words, one opinion can be obtained by performing active monitoring of services which are accessed by service consumer. The second opinion is dependent on user's rating which are provided by service users' manually about his/her direct experience with the service after the successful invocation. Figure 1 shows the cloud service reputation evaluation model which shows the overall process of proposed approach. The presented model is applicable to most of the ratings-based experiences shared on online platforms where users evaluate services with numerical ratings.

The cloud service providers and the cloud service consumers make up the cloud environment with the collaborative ranking system which playing the central role. Trust management comprises three roles, such as the Data Center, Registration Center and Reputation Calculator. The cloud Service providers and the cloud service consumers are all required to register in the registration center before they enter the cloud marketplace. Registration requires provision of essential information which is stored in the data center. For cloud service providers, the essential information includes the cloud service's ID, the function that the service provides and the offered performance of the function. For cloud consumers, it requires personal information typical for user profiles, which we assume is confidential in our model. The Data Center stores the essential information with access rate and also records feedback given by cloud service consumers who experienced a service.

Feedback is denoted as a tuple $F = (Sid, Uid, R, T)$, where Sid represents the identity of the cloud service provider whose services are invoked by the consumer and Uid is the identity of the cloud service consumer who used the Sid. Feedback rating is represented by R provided by the service consumer with integer values in the range (Xu et al., 2015; Elfirdoussi, Jarir & Quafafou, 2012; Li, Zhou, & Yang, 2012; Li, & Wang, 2011). T is a timestamp used to records the time when the feedback was given by the consumer.

The key component in proposed approach is Reputation Calculator, which is able to aggregate the feedback for a cloud service into a reputation score for the service requestor. It is based on the resemblance of preferences between the cloud service requestor and feedback givers. In general, it is unstated that users with higher similarity in their attributes would have a higher probability for attainment of agreement on an indistinguishable thing. Hence, the consumers' with similar feedbacks are more reliable than the universal view in cloud environment.

In this figure, user ratings are collected as feedback to reputation processing node. Following the normalization of feedback data, the feedback ratings are filtered on the basis of similarity categorization. Next, the preferences for abnormal cloud users are set for their specific service requirements. The user preferences mean that the recommendation system provides the most relevant services. There is also a convinced extent of punishment for collusive users, who makes the outcome puzzling when service recommendations are required. The core of the system is the reputation calculation, where we combine the result from filtering with the historical reputation to generate a reputation value that is credible and reliable.

Figure 1. Cloud Service Reputation Evaluation Model

The presented model evaluates the reputation of a service as follows:

$$R(S) = \frac{\sum_{i=1}^n f(i, s) * R_i}{n} \quad (1)$$

Where, $R(s)$ represents reputation score of cloud service s and $f(i, s)$ is the feedback to the s^{th} cloud service from the i^{th} cloud consumer. R_i is the rating of the i^{th} cloud consumer, which is computed based on the similarity between the requestor for the s^{th} cloud service and consumers who have experienced

the s^{th} cloud service and given the feedback. N is the number of consumers who rated the particular cloud service.

Assessing Service Reputation Using Access Rate

Let, $R_{(w_j)}$ is the reputation of a cloud service w_j at time instance t within the limit 0 and 1, i.e., $\forall R_{(w_j)}(t) \in (0,1) \forall R_{l(w_j)}(t) \in (0,1)$. Also, let $R_{(w_j)}(t-1)$, $1 \leq j \leq n$ be the reputation level of w_j at time instance $t-1$, i.e., $\forall R_{(w_j)}(t-1) \in (0,1)$. Let, A_r be the access rate obtained through active monitoring of service invocations w_j to m number of times at time instance t , i.e.,

$$\forall A_r(w_j) \in (1, m) \quad (2)$$

$$\forall R_{l(w_j)}(t-1) \in [0,1]$$

In order to update the old service reputation and compute the newer one $R_{(w_j)}^i(t)$ of a cloud service w_j based on its access rate at t can be obtained as,

$$R_{(w_j)}^i(t) = f(R_{(w_j)}(t-1), A_r, \cup, U_r) \quad (3)$$

$$f(A_r) = R_{(w_j)}^i(t) = \frac{\sum_{i=1}^m f(i, s) * A_r}{m} \quad (4)$$

Where, $f(i, s)$ is the feedback to the s^{th} cloud service from the i^{th} cloud consumer. $R_{(w_j)}(t-1)$ is a previous reputation value at time instance $t-1$, U_r is the user feedback rating, $\cup$ is the propositional logic operator and $R_{(w_j)}^i(t)$ is the i^{th} reputation level at t .

Detection of Malicious User Feedback Rating Using Similarity Computation

Reputation of a cloud service can be determined according to feedback ratings provided by service users. A collaborative filtering method uses user feedback in the evaluation of reputation accuracy of cloud services. Therefore, feedback ratings given by service consumers can not be entirely avoided. But the major issue with user feedback rating is the trustworthiness and accuracy of their feedback. One possible solution towards this problem is to provide an automatic mechanism for detection of malicious user feedback to assess the service reputation by discarding it.

The user feedback rating data is separated into two parts such as, malicious feedback ratings and actual feedback ratings. It can be achieved by setting up the maximum and minimum threshold value for malicious and normal feedback ratings. If the rating provided by majority of users is negative feedback rating then the service reputation is computed on the basis of negative feedback ratings and considered to be of poor reputation. If majority of consumers provides genuine feedback ratings then the service

reputation is computed based on genuine feedback ratings. Here, we have used the simple averaging method to compute the service reputation based on actual user feedback ratings. If the service reputation is evaluated using genuine feedback ratings then this is compared against the ideal reputation in order to include a service in service composition. In this phase, feedback ratings are considered only from trustworthy users for reputation assessment.

Here, manual user feedback is collected from group of consumers for their usage experience with the service. A log file is maintained for user feedback data, with columns user_id and user_feedback rating. Feedback rating is any numeric value between 1 to 5, in which 1 means poor service, 2 means average, 3 means good, 4 means very good and 5 means excellent. Here, feedback data from 15 consumers are collected and analyzed to determine whether it contains any malicious user rating or not. It is necessary to consider only that users rating, which are accurately provided in order to improve the accuracy of reputation of a service.

In online dating service the user feedback ratings are analyzed to identify the occurrence of positive or negative malicious rating providers. For example, if a service user provides the feedback of a service as excellent and majority of users provide the ratings as poor, then the malicious positive rating is removed for further computation of reputation of a service to predict and improve reputation accuracy. This phase works in two steps, first step identifies the list of non malicious users by performing similarity computation of previous user's feedback and second step compares the percentage of non malicious users with the specified threshold value. Related feedback ratings are recognized with similarity computation of previous user's feedback using Pearson correlation coefficient (PCC). Identical feedback ratings are recorded in similarity coefficient variable. Consider that there are m users and n cloud services, and the relationship between users and cloud services is denoted with an m*n matrix. Then each matrix entry $r_{x,i}$ denotes the user feedback rating of the cloud service I rated by the user x, where, $r_{x,i}$ is a normal feedback rating. Below equation is used to calculate the similarity among user x and user y on the basis of their frequently rated cloud services:

$$\text{Sim}(x,y) = \sum_{i \in I_x \cap I_y} (r_{x,i} - \bar{r}_x)(r_{y,i} - \bar{r}_y) / \sqrt{\sum_{i \in I_x \cap I_y} (r_{x,i} - \bar{r}_x)^2} * \sqrt{\sum_{i \in I_x \cap I_y} (r_{y,i} - \bar{r}_y)^2} \quad (5)$$

Where, $\text{Sim}(x,y) \in [-1,1]$ represents the similarity of two users. $I_x \cap I_y$ is a set of commonly rated cloud services by both users a and u. $r_{x,i}$ and $r_{y,i}$ are the two feedback ratings of cloud service i rated by user a and u. $\bar{r}_x$ represents the average feedback rating of all of the cloud services that are rated by user x.

Calculation and ranking of PCC similarity values stuck between the current user and the other users, a set of similar users $S(x)$ can be identified, as follows:

$$s(x) = \{y | \text{sim}(x,y) \geq \text{sim}_k, \text{sim}(x,y) > 0, x \neq y\} \quad (6)$$

Where, Sim_k is the k^{th} largest PCC value with the current user y. k represents the number of the similar users (i.e., higher PCC values than others), and $\text{sim}(x,y) > 0$ is to eliminate the unlike users (dissimilar users, e.g., those with negative PCC value, will influence the reputation measurement accuracy).

After obtaining the set of similar users, according to a set of community cloud services $SS_k = s1k, s2k, \dots, slk$ which contains one services used by the K number of users, the feedback similarity between user a and user u can be calculated as:

$$f(U_r)=FSk(x,y)=\begin{cases} 1-\sqrt{\frac{\sum_{yTS(x)}(r_{x,i}^k-r_{y,i}^k)}{|SS^k|}} & \text{if } |SS^k| \neq 0. \\ 0 & , \text{if } |SS^k| = 0 \end{cases} \quad (7)$$

$$f(U_r)=\frac{\sum_{i=1}^n f(x,i)*R_i}{n} \quad (8)$$

Collaborative Service Reputation Using Propositional Logic

The reputation values obtained from two different sources can further be combined in order to determine final service reputation. Here, $f(U_r)$ represents a function in which service reputation is computed through user feedback and $f(A_r)$ represents a function in which service reputation is computed through runtime access rate. Therefore, the average of the values returned from both the functions $f(A_r)$ and $f(U_r)$ can be taken, and the composition of these two functions generate the final service reputation . Only the services with above a given maximum threshold value ($\text{Max}_{\text{threshold}}$) are provided to cloud service consumer; otherwise, below the threshold value, service is not trustable and not able to discover. In both the cases, old service reputation is updated by the newer one. The reputation of a service can be obtained as:

$$R = [f(U_r) + f(A_r)]/2$$

[Update old service reputation].

$$R_{(w_j)}^i(t) = f(R_{(w_j)}(t-1), A_r, U_r)$$

```

If ( $R \geq \text{Max}_{\text{threshold}}$ ) then
  Discover_service();
Else
  Remove_service (webservice);
End if

```

EXPERIMENTAL ANALYSIS

For performing reliable experiments, we have used large-scale real cloud service dataset named WS-DREAM as shown in Table 1 (Wang et al., 2011; Rathore & Suman, 2013). WS-DREAM dataset is termed as Distributed Reliability Assessment Mechanism which allows cloud service users to carry out service reliability and quality assessment in a collaborative manner. This dataset maintains the service invocation records of 1.5 millions services of 150 users in 24 countries. It also collects non-functional

attributes (e.g., QoS) of these cloud services observed by 339 distributed computers positioned in 30 diverse countries, from Planet-Lab. Here, the number of service invocation parameter of WS-DREAM dataset is considered as access rate. User's rating for some cloud services are directly collected from seekda.com, service-repository.com and xmethod.com. For those services whose rating scores are not available from these sites, we determined their rating scores (e.g., from 1 to 5) based on their OAE-QoS values score (Yuan, An, & Wang, 2009; Rathore & Suman, 2013, 2016, 2017). Here, 1 means poor service, 2 means average, 3 means good, 4 means very good and 5 means excellent.

A list of experiments has been conducted on the proposed ranking mechanism to assess and predict the service reputation over cloud. The performance of presented mechanism is compared with the algorithms proposed in existing approaches (Trang, Zhao, & Yang, 2010; Le-Hung, & Aberer, 2009; Wang, Sun, Zou, & Yang, 2011; Brozovsky, & Petricek, 2007). Mean Absolute (MAE) and Root Mean Square (RMSE) Error is employed as measurement standard to predict service reputation of diverse approaches (Wang, Sun, Zou, & Yang, 2011). MAE and RMSE can be helpful in determining the deviation between the predicted and the observed error in cloud services reputation. The presented approach assess the service reputation based on both manual user's feedback rating and runtime service access rate parameters of WSDREAM dataset. Two experiments are performed in this section to assess the performance of proposed ranking approach. The first experiment is performed on reputation accuracy, whereas the second experiment is performed on deviation of each service from ideal reputation.

Experiment on Accuracy

In this experiment, existing approaches that uses user's feedback rating for reputation assessment of cloud services are compared with the proposed one in order to determine the improved service reputation over cloud (Trang, Zhao, & Yang, 2010; Le-Hung, & Aberer, 2009; Wang, Sun, Zou, & Yang, 2011; Brozovsky, & Petricek, 2007). Existing approaches use user's feedback rating for the service reputation assessment without excluding the malicious feedback ratings, whereas proposed approach detect malicious feedback ratings and computes the cloud service reputation by discarding it. The performance of

presented approach in assessing the service reputation is better than the existing approaches as it does not consider malicious ratings for reputation assessment.

In Figure 2 and Figure 3, ideality line represents the ideal reputation through which the performance of RAP, Reputation Measure approach of Cloud Services (RMWS) and proposed approach can be effectively evaluated. Figure 2 shows the results of service reputation assessment in which only user's feedback rating are included. In Figure 2, there is a significant improvement of approximately 10% in reputation prediction in traditional and existing approaches when considering all feedback ratings (malicious and actual). In traditional reputation assessment mechanism and RAP, service reputation is equal i.e., less than 80%, whereas, in RMWS, it is below 70%. Figure 3 shows the results of assessing cloud service reputation in which the malicious ratings are discarded to provide improved service reputation. As compared to Figure 2, Figure 3 shows the improved reputation accuracy in proposed ranking approach by 20% from RMWS and 10% from RAP. In both the figures, line of ideality represents ideal reputation which is the maximum allowable reputation level.

Figure 2. Accuracy in service reputation in proposed and existing approaches using all user feedback rating

Practically, it is not possible to determine the ideal reputation; instead it can be possible to consider the maximum threshold value to be followed. This means that smaller the deviation is, the approach is more close to the ideality line. As shown in Figure 4, the deviation in proposed approach is smaller than the existing approaches from ideality line. In Figure 4, the deviation in proposed approach is 2.0455 on average, whereas, the deviation of RMWS and RAP on average are 4.737, 9.333 respectively. We compared the performance of proposed approach with the existing approaches under MAE and RMSE measurement criteria (Wang, Sun, Zou, & Yang, 2011). As the dataset is too large to perform experiment, therefore we have considered only a limited number of services which are selected on a random

Figure 3. Accuracy in service reputation assessment in proposed and existing approaches using user feedback rating

Figure 4. Reputation prediction accuracy using MAE

Figure 5. Reputation prediction accuracy using RMSE

basis from the WSDREAM dataset. It can be observed that the MAE and RMSE are smaller in proposed ranking mechanism as compared to RAP and RMWS. A smaller value of MAE or RMSE indicates better service reputation prediction. Figure 4 and Figure 5 shows that the effect of MAE and RMSE is less in proposed approach whereas, RAP and RMWS both has high and equal effect.

FUTURE RESEARCH DIRECTIONS

A series of experiments have been performed to validate the efficacy of proposed approach. It is compared with the existing approaches on the basis of MAE and RMSE measurement criteria in order to determine the deviation between ideal and predicted service reputation. It is observed that the proposed approach has smaller MAE and RMSE as compared to existing approaches from the line of ideality. In practice, it is difficult to determine the ideal reputation, instead a threshold value can be considered to evaluate and validate the efficiency of proposed approach. Proposed ranking mechanism ensures trustworthiness in reputation prediction by combining two different sources to determine the common decision on reputation of service. Although the proposed approach is effective than existing approaches, it also has some limitations, such as overhead of maintaining the records from multiple sources will be increased. There are a few directions for our future work involves combining different trust management techniques to increase the accuracy of trust results and decreasing the overhead of maintaining the records from multiple sources.

CONCLUSION

With the ever increasing services available over cloud, it becomes very difficult to choose the reliable services as per the cloud service consumer's requirements. In this book chapter, a collaborative ranking approach along with a cloud service reputation evaluation model is proposed for reliable discovery and selection of suitable cloud services. It assesses the service reputation using two equally significant parameters, such as access rate and user's rating. It is helpful in reducing the probable unfairness of user ratings and improves the trustworthiness of predicting service reputation in cloud environment. It is also able to detect malicious user's rating and compute service reputation by including only actual user ratings. Proposed approach is validated by conducting several experimental studies using 3,693 real-world services publicly available from the internet. It shows that presented approach distinguished and filtered unfair ratings correctly, as well as it could also recommend suitable services to a specific user based on their preferences in a dynamic market environment.

KEY TERMS AND DEFINITIONS

Access Rate: The rate of total number of cloud service request requested by the cloud service consumer.

Cloud Computing: A platform where one can find all kind of services at one place through internet.

Cloud Service Consumer: An entity who utilizes cloud services.

Cloud Service Provider: An entity who offers cloud services over cloud.

Collaborative Filtering: An automated predictive method of collecting preferences from many users based on their interest.

OAE-QoS: An overall aggregated score of all QoS parameters of a cloud services.

Quality of Service: The overall description of the performance of a cloud service.

Rater's Credibility: The quality of the service that makes cloud service consumers or providers to trust the information or service.

Reputation: An opinion about a cloud service by cloud consumer based on its previous history.

Root Mean Square and Mean Absolute Error: The deviation between the predicted and the observed error in measuring cloud services reputation.

Trust: A belief among cloud service consumer and provider about the reliability of cloud services.

Tuning Drone Data Delivery and Analysis on the Public Cloud

2

Jose Lo Huang

Simon Bolivar University, Venezuela

INTRODUCTION

There has been great growth in the use of drones for research. The drone is “a remote-controlled pilotless aircraft or missile” capable of visualizing extended areas of study in less time than the human eye (OxfordDictionaries.com, 2018). Many drones can send live video streaming to mobile phones or computers. Data collected by drones provides useful information and patterns to deploy new technologies and generate deeper data analysis. These data, including information on movement, color, or area patterns, can be processed per frame and mapped as color pixels or represented as a set of Extensible Markup Language (XML) files.

According to Mell and Grance (2011, p. 2) from the National Institute of Standards and Technology (NIST):

Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.

The public cloud, such as Amazon Web Services (AWS) or the Google Cloud Platform (GCP), offers reliable and nearly unlimited storage (www.aws.amazon.com). Paid on-demand services can be used as additional storage or compute services. Users can create several parallel virtual machines and process data loads through the public cloud. It is possible to automatically scale the use of virtual machines depending on resource needs (www.aws.amazon.com).

Photogrammetry is the use of photography in surveying and mapping to ascertain measurements between objects (OxfordDictionaries.com, 2018) and is an example of how a machine can be used to process images collected from drones. Monthly data can be efficiently processed by integrating and analyzing terabytes (TB) or petabytes (PB) from drones on the public cloud. However, there is not a faster way to send large amounts of data from a premise server to the public cloud.

The current method of processing data from drones on the cloud use raw data and these were sent in sequential order. This method depends on the speed of transference of every packet from the base station to the cloud. Also, if the company use only one node in the cloud for processing, then the overall process is sequential and very slow. This amount of time could be very long with a regular video of 300 MB. Using a set of videos of regular size can take several hours or days, depending on the bandwidth and the flow between the intermediate network devices.

In this article, the researcher will use a set of tools and an automation process to study a unique method of compress the output of drone videos and improve the transference of data from the on-premise base station to the cloud to analyze them in a concurrent environment on the public cloud. After discussing alternatives, the chapter will review process data calculations to compare faster methods. With modifica-

DOI: 10.4018/978-1-7998-3479-3.ch016

tions to upload times, the analyzed data time is reduced by an average of 78% as compared to a common sequential process. This valuable time can be used by companies to be focused on their experiment and business results instead of the processing of the data sets.

BACKGROUND

Several studies have discussed the integration of drones or robots and the public cloud. In the internet of drones theory (Gharibi, Boutaba, & Waslander, 2016), the authors created a system to manage and control access to drones and their activities to navigate service locations. A study by Yinong and Garcia (2010) reviewed the field of robots as a service in cloud computing. Through distributed systems, the researchers controlled a network of segregated robots and sent various programs to the robots to deliver different services.

In a service-oriented architecture (SOA) study, researchers created a Web-based system hosted in the public cloud to manage drone networks (Koubaa, Qureshi, Sriti, Javed, & Tovar, 2017). In a robust study by Mahmoud, Mohamed, and Al-Jaroodi (2015), the authors designed a technological system using unmanned aerial vehicles (UAVs) as nodes based on the theory of the internet of things (IoT). Using the RESTful HTTP technology and Arduino boards, the UAVs transmitted data with the internet.

Just a few years before these studies, pilots could not use drones from a distance. However, distance no longer limits the user. It is common practice to use data collected by sensors in wireless devices. For example, Lo, Lopez, Goncalves, and Perera (2015) fetched data with several types of sensors analyzed with the Skyline algorithm. This study had collected a large amount of data from sensors and stored them in local systems to be analyzed with the algorithm. Although, with this method the researchers had to have the hardware to process the data. Nowadays, data scientists have the option to take advantage of the better and on demand resources in the cloud to analyze faster and a huge quantity of data. For example, in a research made by Saleem, Salim, and Rehmani (2014) they explain the integration between Wireless Sensor Networks (WSN) and the public cloud. Applications of WSN over the cloud are then described in that study.

The development of theories about the improvement of the work done on the cloud was studied in different researches. For instance, the research made by Bitam (2012) where the author has been studied and solved, with the Bees Life Algorithm, the job scheduling problem in the cloud using a method simulating the behavior of the bees in the nature. Another interesting study can be found in the research about a cloud-enabled robotic system for real-time video tracking applications made by Liu, Chen, Pham, Shen, and Chen (2014). In this study, the researchers used effectively the cloud computing resources to accomplish more computationally intensive tasks of a set of robotic systems. They used a cloud enabled robotic system (CERS) framework to process images from a processing application.

There are some studies about the processing of images on the cloud with the security as the main concern. For example, in the research conducted by Sattar, Adnan, and Kali (2017), the focus of the experiment is maintaining a secure environment inside the cloud when processing a data set. In a research developed by Welsh (2016), the author compares the processing time of a big set of images in local hardware (8 weeks) and the same data set in a server farm on the cloud (few hours). He used high quality images in different formats as 3D or 4K.

Although researchers have studied image processing, drones and the public cloud before, they have not mentioned the latency and time to send data from on premise to the cloud. This may be due to small data samples or the exclusion of this information from their studies. When research includes large amounts of

data, there is a need to tune and improve transmission times between local machines and public clouds because the time spent in the transference is high. In this paper, the author presents a robust method to tune the process of send and analyze the images from drones on the public cloud.

FOCUS OF THE ARTICLE

It is common for scientific studies to use drones to review images in a specific area. After the videos was completed, they stored them in local devices to process them or take advantage of the public cloud to gain more resources to speed up the process of the final videos. When they use the public cloud, the more common way of send the information is in sequential mode. This is, one by one using a First In First Out (FIFO) mechanism. And when the videos arrived at the cloud, the common method to process them is using one server instance with enough resources in terms of CPU and RAM memory.

With large amount of data sets, this sequential process is not enough to analyze the data in a good time. For this reason, this paper develops a new way to transfer the images and processing them on the cloud. This process includes techniques as compression, concurrency and autoscaling.

In this article, the author explains with an experimental work, how to tune two core processes to analyze drone data in the public cloud. First, the study analyzes and tunes the transmission of drone data to an on-premise base station, as well as the transmission of data from an on-premise station to public cloud machines. Second, tunes the process of analyzing data on the public cloud. In the end of the research, there are some results about how the tuning improves the current regular process.

Hardware

The hardware used in this research was composed of eight drones DJI Phantom 3 Standard, eight MacBook Pro 2015 with an Intel Core i5 processor, 16 GB RAM and 2 GB video GPU each. Each drone took videos in one of these cities: (1) Caracas, Venezuela; (2) Maracaibo, Venezuela; (3) Cancún, Mexico; (4) Santo Domingo, Dominican Republic; (5) Bogota, Colombia; (6) Quito, Ecuador; (7) Sao Paulo, Brazil; and (8) Buenos Aires, Argentina. The transmission used an independent program developed by the author. Drone videos were sent in divided frames.

Each MacBook was aligned with a drone to send transformed frames to the public cloud, specifically an AWS account. The author used an external storage device with each MacBook. Eight devices detected DJI radio frequency with eight Arduino boards.

Concerning the public cloud, the author used three to eight t2.xlarge Elastic Compute Cloud (EC2) instances with four virtual central processing units (vCPUs) and 16 gigabyte (GB) of random access memory (RAM) using Amazon Machine Images (AMIs). The complete list of EC2 instances in AWS can be found online (www.aws.amazon.com).

Software

The software/services developed and used by the author includes:

- **DRON2PREM:** This software was developed in C language by the author of the article to read every frame from the drone using a live streaming feature. It is automatically saved in an external

device connected to one MacBook Pro. This software decodes the drone's video frames with a wireless sensor at the same radio frequency.

- **PREM2CLOUD:** This software was developed in C language by the author of the article to run at the same time as DRON2PREM. This program compresses the final videos with 7z. This process may be slower than other compress methods due to the final file size. After compressing it in multiple parts, it uses AWS Command Line Interface (CLI) to simultaneously send files with several threads. The files are allocated in a Simple Storage Service (S3) bucket.
- **CLOUD2VALUE:** This software was developed by the author of the article to analyze data on the cloud. The program, which was written in Python language, transform every drone video frames file allocated in the S3 bucket to XML files and processes every XML to search for patterns. This software can use some machine learning processes and detects desired patterns. For example, in this article, it is used to review the areas searching for red points.

The software/services developed by external companies include:

- **Amazon Web Services:** These services were used to develop experiments. The author used several AWS services, including Simple Storage Services (S3), Elastic Load Balancer (ELB), and Autoscaling.
- **Tsunami UDP:** This service is a “fast user-space file transfer protocol that uses TCP control and UDP data for transfer over very high speed long distance networks (³ 1 Gbps and even 10 GE), designed to provide more throughput than possible with TCP over the same networks” (Wagner, 2009, para. 1).

IMPLEMENTATION

The project's implementation includes complex steps. In the first part, the author creates a program with Python, C, and Bash programming languages to obtain data from DJI drone transmission. Radio frequency sensor device technology was required to decode data frames sent by drones. These devices were created locally using Arduino boards. They were connected to the machines via a universal serial bus (USB) port. An instance of the DRON2PREM program runs in the local machine. It saves the drone's data from the Arduino boards. These data frames are saved as a compressed file inside an 8 TB external device.

At the same time, an instance of PREM2CLOUD is running. When DRON2PREM has written the final message in the current log file of the current thread, the PREM2CLOUD instance divides the file into eight parts. This creates a multi-parallel connection with the AWS S3 bucket to send parts via channel created with different network interface cards.

There is a listener waiting for new connections in the CLOUD2VALUE program in an EC2 instance in AWS platform. When a new connection arrives, the CLOUD2VALUE software waits to finish the message in the transfer log file of the PREM2CLOUD. After the PREM2CLOUD finishes the copy from an on-premise machine to the S3 bucket, the CLOUD2VALUE link the eight pieces of the compressed video. The CLOUD2VALUE will uncompress the file and place it in a local (for the EC2 instance) elastic block storage (EBS) device for the hard process.

The CLOUD2VALUE program reads the video frames. For every frame, it produces an XML file with color information on every pixel of the frame. The author used the red-green-blue (RGB) system

to process pixel colors. After every frame is processed, the author's neural network (NN) Drone Image Processor (DrImPro) program will search the requested input.

The experiment includes auto scaling, which is a new feature of the public cloud. This feature balances the process between multiple nodes (EC2 instances). If necessary, it creates new EC2 instances to help in the process. For example, if the current project has three EC2 instances with all instances using 100% CPU, the auto scaling feature can create new EC2 instances to balance the processing load.

Another test was created with experimental drones (different from DJI). This test evaluates the transmission between the drone and the on-premise machine with the DRON2PREM (not restricted to DJI brand drones). For these tests, the author used Raspberry Pi boards connected to visual sensors to construct the drones.

At the end of the experiment, the program reveals the summary of every node in the machine learning (ML) network and the process. Figure 1 illustrates the global process.

Figure 1. Global process of the tuning and analyzing portions

RESULTS

The experiments selected for this article are:

- Find the areas with more red points (basic experiment).
- Find the areas with more blue points (simulating water).
- Find the areas with more cars (simulating traffic).

The researcher ran the experiment in different combinations to demonstrate the hypothesis of the improvement of the process with the new method. The main combinations are:

1. Eight DJI drones, eight MacBook Pro laptops, on-premise NN processing
2. Eight DJI drones, eight MacBook Pro laptops, one copy thread per laptop, three to eight EC2 instances as nodes in the NN
3. Eight DJI drones, eight MacBook Pro laptops, eight copy threads per laptop, one EC2 instance as nodes in the NN
4. Eight experimental drones, eight MacBook Pro laptops, eight copy threads per laptop, three to eight EC2 instances as nodes in the NN
5. Eight DJI drones, eight MacBook Pro laptops, eight copy threads per laptop, three to eight EC2 instances as nodes in the NN

Every test uses an average of 1.5 TB of raw data in total. When transformed to XML files, the size was reduced to an average of 18 GB. Using those experiments, the author can prove the method's improvement in translating the processing to the cloud and using auto scaling to benefit research.

Figure 2 illustrates the results. The first experiment used eight DJI drones; it executed three programs (i.e., DRON2PREM, PREM2CLOUD, and CLOUD2VALUE) in on-premise machines. They saved compress time, decompress time, and time spent sending the video to the public cloud. However, the difference in time was not significant because it used a local network with less bandwidth than the public cloud network. The experiment required a huge amount of costly resources. The experiment's result values were 15 hours, 27 minutes, and 13 seconds.

In the second experiment, the author aimed to show slow processing when using only one thread, which is the common technique. However, the author did not employ auto scaling. Without auto scaling, the time to complete the task was very high (greater than five days). Time was invested in the network when transmitting compressed files. The total time for the second experiment was 39 hours, 15 minutes, and 35 seconds. This employed a 1 GB/s network link.

On the other hand, the third experiment demonstrated the value of auto scaling. In this example, the author used only one EC2 instance in the public cloud to process all data. The time was high (25 hours, 19 minutes, and zero seconds).

In the fourth experiment, the researcher aimed to experiment with custom programs and custom drones created by electronical and computer engineers. They used Raspberry Pi boards as the core body of the drones. Several sensors (video, Bluetooth, and GPS) connected to perform the experiment. The results were impressive as the process was completed in nine hours, 11 minutes, and five seconds with the use of eight threads of network transmission and auto scaling.

In the final experiment, the author used their best resources, including eight DJI drones, eight laptops as local receivers, eight threads of network copy, and three to eight EC2 instances using auto scaling on the AWS public cloud. With these parameters, the complete process was executed in eight hours, one minute, and five seconds.

With the results of this study, companies and regular researchers can have a new alternative to improve their transference process of drone videos (or another types of videos) to be processed on the public cloud. Also, they have a better method of processing data using the Autoscaling feature of Amazon Web Services. With this advanced method, the process of analyzing data from drone videos on the public cloud reach a 78% of improvement. This is considerable time to spent in other tasks more related with the interpretation of the results or the output.

Figure 2. Comparison of time invested in complete processing using different methods

SOLUTIONS AND RECOMMENDATIONS

During the experimental evaluation, the researcher must confirm that other drones do not exist in the UAV area due to the risk of failed transmission. The reception of drones' transmission packets can capture packets from other drones in the air. This will result in a failed experiment. A solution for this situation is send the drone packets in a different radio frequency and another channel instead of the default of the brand, only if this is a permitted behavior of the hardware involved. For this experiment, the author checked the area before, during, and after the experiment. Other drones were not present within 500 meters of the round ratio. Therefore, the experiment was highly reliable.

Another recommendation for new experiments is to use a virtual private network (VPN) for transmission from on-premise machines to the public cloud. VPNs allow for better performance and security in the transport of drone data. This article's experiments did not use security cryptographic algorithms or keys. The author used the default device environments.

FUTURE RESEARCH

Using this article, researchers who are interested in drones and public cloud development can obtain valuable resources to expand tests. For example, this study did not cover the scope of different drone brands (i.e., Blackhawk, Altar) or public cloud platforms (i.e., Google Cloud Platform, Microsoft Azure). An extension of this study can compare transmissions using different platforms as variables. Future studies can evaluate which platform is best for neural network or machine learning with drone image processing.

The author is working on an extension of this study. It will include the development of a mechanism to detect a specific face among hundreds of individuals. As the drone flies and sends image frames to the station and the public cloud for processing, the cloud program will process images. Along with the machine learning and big data processing, the program should provide specific coordinates to locate the person in the picture.

To review the software in Python or C used, they can be found in the webpage of the project, listed in the references section. It uses a GNU General Public License (GPL) for the source code of every component.

CONCLUSION

In this chapter, the author created a complex way to optimize the processing of long drone videos on the public cloud using several GB or TB per video. The researcher's system collects a drone-captured video, sends the data to a local on-premise machine, tunes transmission of the video to the public cloud, transforms the videos to XML files, and creates a custom program to search and find points of interest in every frame to indicate a specific point. The author tuned the normal process an average of 78% of the time.

The results in this study have several practical implications, for instance, they can be very useful in academic researches about environment. The process of analyzing biological, weather or environment data from on premise machines to the cloud is expensive and slow. Another example could be the process of rendering and editing movies or television series on the cloud. When the team record the videos and the platform or application is allocated on the cloud, they have to send all the scenes to the platform. After that, they can edit the videos. With this new method, the process would improve in cost and time.

INTRODUCTION

Complex software systems typically involve many interacting applications, with many decisions to take and many tradeoffs to evaluate, not only in each application but also in the ways in which the various applications interact. Ideally, applications should be completely decoupled, with no constraints on one another and completely independent lifecycles. This would allow separate development of each application and elimination of design and programming inefficiencies due to interaction between the specifications of applications, which usually cause iterations in requirements for other applications and consequent changes.

However, applications do need to interact and to cooperate, to collectively fulfill the goals of the system. Therefore, a fundamental tenet in software design is to reduce application coupling as much as possible (Bidve, & Sarasu, 2016) without hindering the interaction capabilities necessary to support the required application interoperability. Application decoupling has also the advantage of improving:

- § **Changeability:** A change in one application is less likely to have a significant impact in other applications.
- § **Adaptability:** Fewer constraints require less effort to adapt to changes in other applications.
- § **Reusability:** An application with fewer requirements and constraints has an increased applicability range.
- § **Reliability:** A smaller set of requirements simplifies the task of finding an alternative application in case of failure.

In general, the fundamental problem of application design, in terms of interaction, is how to provide (at most) the minimum coupling possible while ensuring (at least) the minimum interoperability requirements. Therefore, the main goal is to ensure that each interacting application knows just enough about the others to be able to interoperate with them but no more than that, to avoid unnecessary dependencies and constraints. This is an instance of the principle of least knowledge (Hendricksen, 2014).

The two most used application integration approaches, Service-Oriented Architecture (SOA) (Erl, Merson, & Stoffers, 2017) and Representational State Transfer (REST) (Fielding, Taylor, Erenkrantz, Gorlick, Whitehead, Khare, & Oreizy, 2017) hardly comply with the principle of least knowledge. They achieve interoperability but do not solve the coupling problem, since they require, in practice, that the schemas used by the interacting applications are the same.

SOA is good at modeling distributed systems based on the service paradigm (an extension the object-oriented paradigm for distributed applications) but involves rather complex and static service specifications and entails sharing schemas between client and server, which is a heavy form of coupling. Changing the

DOI: 10.4018/978-1-7998-3479-3.ch017

interaction between Web Services is not a trivial task. REST is much simpler, justifying its increasing popularity, but is rather low level and not the best match for general-purpose, behavior-oriented distributed applications. It also entails a high level of coupling, since it requires that both interacting applications share the same media type specification.

This article revisits the application integration problem with an open mind, without *a priori* restrictions from specific technologies, such as Web Services for SOA and RESTful APIs for REST. The only assumption is that there are applications that need to interact, by using messages. The idea is to base the interoperability mechanism on the concepts of *compliance* (Czepa, Tran, Zdun, Kim, Weiss, & Ruhsam, 2017) and *conformance* (Carmona, van Dongen, Solti, & Weidlich, 2018), which allow partial interoperability, rather than on sharing data schemas. This makes all the difference. Unlike Web Services, there are no declared schemas that a client is forced to use in their entirety. Unlike RESTful applications, the client and server do not have to agree on a specific data type. Each resource (dataset, message or distributed application) has its own schema, stemming from its service (interface) definition. Checking for interoperability between two resources (for example, between a message and the parameter required by an operation) is done structurally, component by component, recursively until primitive resources are found.

The rest of the article is structured as follows. It starts by establishing a simple interoperability framework, with the various abstraction levels at which interoperability must be established. After defining the fundamental problem of application integration, the two most common solutions, SOA and REST, are analyzed and compared, in particular in what coupling is concerned. Compliance and conformance are then presented and proposed as a solution to reduce coupling to the bare minimum required by the interacting applications.

BACKGROUND

Modern applications, designed and managed in a distributed way, need to interact and collaborate with an increasing scale, since systems are becoming more complex and diversified. Digital-based technologies, such as cloud computing (Varghese, & Buyya, 2018), mobile computing (Page, & Thorsteinsson, 2018), and the Internet of Things (Paul, & Saraswathi, 2017) became ubiquitous and disruptive. In the recent 4.0 trend (Dornberger, 2018), collaboration means generating and exchanging more and more data, either at business, personal, or sensor levels. The fourth industrial revolution, commonly known as Industry 4.0 (Liao, Deschamps, Loures, & Ramos, 2017), in which agile reconfigurability of the production supply chain is a fundamental objective, is just an example.

All this raises the application integration problem to a completely new level, in which conventional integration technologies expose their limitations and require new solutions.

Integration (Panetto & Whitman, 2016) can be broadly defined as the act of instantiating a given method to design or adapt two or more systems, so that they cooperate and accomplish one or more common goals. To interact, applications must be interoperable, i.e., able to meaningfully operate together.

The ISO/IEC/IEEE 24765 standard (ISO, 2010) defines *interoperability* (Agostinho, Ducq, Zacharewicz, Sarraipa, Lampathaki, Poler, & Jardim-Goncalves, 2016) as “the ability of two or more systems or components to exchange information and to use the information that has been exchanged”. Therefore, merely exchanging information is not enough. Interacting applications must also be able to understand it and to react according to each other’s expectations.

A related problem is *coupling* (Bidve, & Sarasu, 2016), which provides an indication of how much applications are intertwined and depend on each other. Some degree of coupling is unavoidable, since

some form of mutual knowledge is necessary to make interoperability possible. Interoperability and a coupling as low as possible need to be combined to achieve an effective and efficient integration of distributed applications.

The two most used integration approaches are the Software-Oriented Architecture (SOA) (Erl, Merson, & Stoffers, 2017) and Representational State Transfer (REST) (Fielding, Taylor, Erenkrantz, Gorlick, Whitehead, Khare, & Oreizy, 2017), with the corresponding technological solutions for distributed interoperability, Web Services (Zimmermann, Tomlinson, & Peuser, 2012) and RESTful APIs (Pautasso, 2014), respectively.

Unfortunately, the discussion involving SOA and REST (Bora & Bezboruah, 2015) usually entails more technological issues than conceptual or modeling arguments. There are also several proposals to integrate SOA and RESTful services (Dahiya, & Parmar, 2014; Sungkur, & Daiboo, 2016).

Web Services and RESTful APIs are based on data description languages such as XML (Fawcett, Ayers, & Quin, 2012) and JSON (Bassett, 2015). Although these languages have achieved the basic objective of interconnecting independent and heterogeneous systems, supporting distributed application interoperability, they are not effective solutions from the coupling viewpoint, since they require that the data schemas of the messages exchanged by the interacting applications are the same.

Several metrics have been proposed to assess the maintainability of service-based distributed applications, based essentially on structural features, namely for service coupling, cohesion and complexity (Babu, & Darsi, 2013). There are also approaches trying to combine structural coupling with other levels of coupling, such as semantics (Alenezi, & Magel, 2014).

Compliance (Czepa, Tran, Zdun, Kim, Weiss, & Ruhsam, 2017) is a concept that can be used as the foundation mechanism to ensure partial interoperability and thus minimize coupling. It has been studied in specific contexts, such as choreography (Capel & Mendoza, 2014), modeling (Brandt & Hermann, 2013), programming (Preidel & Borrmann, 2016), and standards (Graydon, Habli, Hawkins, Kelly, & Knight, 2012). Conformance (Carmona, van Dongen, Solti, & Weidlich, 2018) is another concept underlying partial interoperability, enabling an application to replace another if it conforms to it (supports all of its features).

A Simple Interoperability Framework

Most interoperability technologies, such as Web Services (Zimmermann, Tomlinson, & Peuser, 2012) and RESTful APIs (Pautasso, 2014), usually consider only the syntactic format of messages, or at most the semantics of its terms (Wang, Gibbins, Payne, Patelli, & Wang, 2015). However, the ability to meaningfully interact involves higher levels, naturally including behavior. Table 1 establishes a linearized systematization of interoperability at several levels of abstraction. The higher levels are particularly relevant when complex, enterprise-class applications are involved.

All these abstraction levels are always present in all application interactions, even the simplest ones. There is always a motivation and purpose in sending a message, an effect stemming from the reaction to its reception, a meaning expressed by the message, and a format used to send it over a network under some protocol. However, what happens in practice is that some of these levels are catered for *tacitly* (implicitly assumed) or *empirically* (explicitly hidden underneath some existing specification).

Also relevant is non-functional interoperability. It is not just a question of invoking the right operation with the right parameters. Adequate service levels, context awareness, security and other non-functional issues must be considered when applications interact, otherwise interoperability will be less effective or not possible at all. The abstraction levels of Table 1 must be considered for each of these concerns.

Table 1. Abstraction levels and layers of interoperability

Abstraction level	Layers	Description
Symbiotic (purpose and intent)	§ Coordination § Alignment § Collaboration § Cooperation	§ Motivations to interact, with varying levels of mutual knowledge of governance, strategy and goals.
Pragmatic (reaction and effects)	§ Contract § Workflow § Interface	§ Management of the effects of the interaction at the levels of choreography, process and service.
Semantic (meaning of content)	§ Inference § Knowledge § Ontology	§ Interpretation of a message in context, at the levels of rule, known application components and relations, and definition of concepts.
Syntactic (notation of representation)	§ Structure § Predefined type § Serialization	§ Representation of application components, in terms of composition, primitive components and serialization format of messages.
Connective (transfer protocol)	§ Messaging § Routing § Communication § Physics	§ Lower level formats and network protocols involved in transferring a message from the context of the sender to that of the receiver.

The Fundamental Problem of Application Integration

Applications that interact in a distributed environment require some network to send each other messages. In each message transaction (sending a request and processing a response), both sender and receiver need to understand and react appropriately upon receiving request and response messages, at all abstraction levels of Table 1.

A given application, in the role of server, publishes the set of request messages to which it is able to respond, which defines the interface of the functionality offered by that application (its Application Programming Interface – API). In the role of client, another application may send one of the acceptable request messages to the server and invoke the corresponding functionality. Applications can also express their APIs in terms of exposed features, such as operations. Each operation can accept its own set of request messages.

The server needs to be able to understand the client's request and to react and respond according to what the client expects. Otherwise, the interaction will not produce the intended effects.

Coupling expresses the mutual dependencies between applications, stemming from the need to understand messages. The goal is to reduce it as much as possible, to avoid unnecessary constraints to the evolution and variability of applications. However, what can be achieved is a balance between two contradictory goals:

- § On the one hand, two completely uncoupled applications can evolve freely and independently, which favors adaptability, changeability and even reliability (if one fails, there is no impact on the other).
- § On the other hand, applications need to interact to cooperate towards common or complementary goals, which means that some degree of previously agreed mutual knowledge must exist. The more they share with the other, the easier interoperability gets, but the greater coupling becomes.

The fundamental problem of application integration is how to provide *at most* the minimum coupling possible, while ensuring *at least* the minimum interoperability requirements. The main goal is to ensure

that each interacting application knows just enough about the others to be able to interoperate with them but no more than that. Unnecessary dependencies and constraints should be avoided.

Existing data interoperability technologies, such as XML and JSON, assume that interacting applications share the same message schema. This is reminiscent of the first days of the Web and HTML documents, in which the client read the document produced by the server and both needed to use the same data specification. Today, data have been separated from their specification (schema), but both client and server still work on the same information. Decoupling has not improved.

The problem is that a server may need to serve several potentially different clients and a client may need to send requests to several potentially different servers. Sharing a schema couples both client and server for the whole set of messages that the schema can describe, even if the client only uses a subset of the admissible requests and the server only responds with a subset of the admissible responses. Client and server are therefore more coupled than needed and changes in one application may very likely imply changing the other as well, even if a change does not affect the actually exchanged messages.

Current Solutions to the Application Integration Problem

SOA (Erl, Merson, & Stoffers, 2017) and REST (Fielding, Taylor, Erenkrantz, Gorlick, Whitehead, Khare, & Oreizy, 2017) are the most popular architectural styles today in the integration of distributed applications.

SOA appeared in the context of enterprise integration, with the main goal of achieving interoperability between existing enterprise applications with the then emerging XML-based technologies, more universal than those used in previous attempts, such as CORBA (Common Object Request Broker Architecture) (Henning, 2008) and RPC (Kukreja & Garg, 2014). It was a natural evolution of the object-oriented style, now in a distributed environment and with large-grained resources to integrate. Therefore, the emphasis was put on modeling applications as black boxes, exposing their external functionality with an interface composed of a set of operations, application dependent. Internal structure was avoided, as a measure to reduce coupling by applying the information hiding principle.

REST appeared in the context of Web applications, as a systematization of the underlying model of the Web and with scalability as the most relevant goal, since interoperability had already been solved by HTML (and, later, XML and JSON) and HTTP. REST is based on several architectural constraints, the most relevant of which are stateless interactions (only the client maintains the interaction state) and uniform interface (all resources have a service with the same set of operations, with variability on structure and with links to resources, rather than on service interface). These constraints have decoupling between a server and its clients as their main motivation, to support scalability. When potentially thousands of clients connect to a server, server applications need to be able to scale and to evolve as needed and as independently as possible from the clients.

Coupling was therefore a main concern for both architectural styles, although this has not prevented a lively debate between proponents of SOA and REST. In particular, REST has been heralded as much simpler and providing a better decoupling between interacting applications (Pautasso, Zimmermann, & Leymann, 2008). A simple example, however, indicates that these two architectural styles are not that different, in essence.

Figure 1a describes a typical online product purchase scenario, using the process paradigm and Business Process Modeling Notation (BPMN) (Chinosi & Trombetta, 2012) to illustrate the interactions between a customer, a seller, and a logistics company to deliver the product.

Figure 1. An example of business-level distributed interactions (a), with a model of the customer process in (b) SOA and (c) REST styles

(a)

(b)

(c)

Each of the three roles in this process choreography needs to be conceived, designed and implemented as much independently as possible, since each role can be performed by applications with different goals and characteristics, which means that coupling should be minimized.

This example can be used to compare the approaches based on SOA and REST. Figure 1 details just the Customer process, for simplicity, using UML. Figure 1b represents the SOA approach, with a resource structure mimicking the three actors and the corresponding sequence diagram, reflecting their interactions. The REST approach goes directly to modeling interaction states, which is reflected in Figure 1c by a state diagram.

Apart from details, it is noticeable that the flow of activities of the customer in SOA is dual of the flow of states in REST. Figure 1b (SOA) uses an activity-based flow graph, with activities performed at the nodes and state changed at the edges, whereas Figure 1c (REST) places state at the nodes and implements activities at the edges.

SOA is guided by behavior and REST by (representation of) state. In UML terminology, SOA uses a static class diagram and a sequence diagram (Figure 1b) as a first approach, to specify which resource types are used, to establish the set of operations provided by each, and their interactions, whereas REST

starts with a state diagram (Figure 1c), without relevant concern about distinguishing which state belongs to which resource. In the end, they perform the same activities and go through the same states, although with different perspectives that stem from the approaches used to solve the same problem.

It is also clear that both SOA and REST tackle the fundamental problem of application integration, to achieve interoperability while trying to minimize coupling and to comply with the information hiding principle by hiding the implementation of individual resources:

- § SOA's approach is to hide resource structure (considering it part of the implementation), whereas REST's approach is to hide resource behavior (its service) by converting it into resource structure (each operation is modeled as a resource).
- § SOA models resources as close as possible to real world entities, to reduce the semantic gap (Sikos, 2017). Since these are different from each other, offering a specific set of functionalities, the result is a set of resources with different interfaces (different set of operations). The client must know the specific interface of the server. This entails coupling and may only be acceptable if the number of clients for a given server is usually reasonably small and the system evolves slowly (to limit the maintenance effort).
- § REST tries to avoid the interface coupling by decomposing complex resources into smaller ones (with links to other resources) until they are so primitive that they can all be treated in the same way, with a common interface. The interface diversity is transferred to the richness of the structure of the links between resources. This uniform interface for all resources, with a common set of operations, is the most distinguishing feature of REST. This corresponds to separating the mechanism of traversing a graph (the links between resources) from the treatment of each node (resource). The goal is that a universal link follow-up mechanism, coupled with a universal resource interface, leads to decoupling between server and clients, allowing servers to change what they send to the clients because these will adapt automatically, by just navigating the structure and following the links to progress in the interaction process.

Unfortunately, both SOA and REST have fallacies and limitations:

- § SOA assumes that all resources (applications) are at the same level and that exposing their services is just providing some interface and the respective endpoint. The fallacy is to assert that resource structure is unimportant. This may be true when integrating very large-grained resources, but not in many applications that include lists of resources that need to expose their services individually. The limitation is in changeability. Changing the interface of the server will most likely require changes in the clients as well.
- § REST imposes a uniform interface, which allows treating all the resources in the same way. The fallacy is to consider only a syntactic interface, or even semantic (Verborgh, Harth, Maleshkova, Stadtmüller, Steiner, Taheriyani, & Van de Walle, 2014), but forgetting behavior (higher levels in Table 1). The reaction of resources to requests also needs to be considered, which means that following a link cannot be done blindly. The client needs to know which kind of reaction the server is going to have. In the same way, traversing a structured resource implies knowing the type of that resource, otherwise which link should be followed next may not be known. This means that all types of resources to be used must be known in advance, either standardized or previously agreed upon (with custom media types). This is a relevant limitation of REST. What happens in practice is that developers are more than happy to agree on simple resource structures and on an aligned

API to match. REST's advocates contend that an API should be represented simply by its initial link (an URI – Universal Resource Identifier –, for example) and all the functionality should be dynamically discovered by the client by exploring links. However, this can only be done with a fixed set of resource types (predefined or previously agreed upon). Resource structure can vary, a good advantage of REST, but only within the boundaries of resource types known in advance. This is nothing more than sharing schemas, which means coupling.

SOA is a better option for large-grained, slowly-evolving complex resources, whereas REST is a better option for small-grained, structured resources that are relatively simple. In search for simplicity and maintainability, many service providers (including cloud computing providers) have stopped using SOA APIs in favor of REST, by modeling operations as resources, using naturally occurring lists of resources as structured resources with links, and dynamically building URIs instead of resorting to operation parameters. Decoupling in REST, however, is not as good as its structure dynamicity seems to indicate. All the resource types (media types, in REST terminology) must be known in advance and the client may break if a new media type unknown to the client is used by the server. In addition, even when the type is known, the client cannot invent what to do and which link to choose when it receives a resource representation of a given type. Collaboration requires that both server and client implement behavior and deal with its effects, which means that they cannot be agnostic of each other, but rather need to be designed to work together.

Minimizing Coupling With Compliance and Conformance

With current integration technologies, interacting applications must share the schemas of the messages that they exchange. This leads to a higher level of coupling than actually needed, since applications are constrained by the whole set of features of those schemas, even if not all are used.

This article proposes an alternative approach, in which the schema of a message, as generated by the sender, needs only partially match the schema of the messages expected by the receiver. Only the actually used features need to have a match. Features present in the message but not required by the receiver are ignored. Optional receiver features not present in the message are assigned default values prior to processing the message at the receiver. In addition, structured features are checked structurally and recursively, component by component.

This means that a client can use (send request messages to) various servers, as long as these messages match the relevant parts of those servers' request schemas, even if they were not designed to work together. In addition, a server can be replaced by another one, with a different schema, as long as it can deal with all the requests that the replaced one could. The replacement can occur due to evolution of the server to a new version or by resorting to another, similar server, probably for load balancing.

These *use* and *replace* relationships lead to two important schema relations, illustrated by Figure 2:

- § **Client-server: Compliance** (Czepa, Tran, Zdun, Kim, Weiss, & Ruhsam, 2017). The client must satisfy (*comply with*) the requirements established by the server to accept requests sent to it, without which these cannot be validated and executed. It is important to note that any client that complies with a given server can use it, independently of having been designed for interaction with it or not. The client and server need not share the same schema. The client's schema needs only to be compliant with the server's schema in the features that it actually uses. Since distributed applications have independent lifecycles, they cannot freely share names, and schema compliance must

be checked structurally, feature by feature, between messages sent by the client and the interface offered by the server. Note that in a response the roles of schema compliance are reversed (the server is the sender and the client is the receiver).

- § **Server-server: Conformance** (Carmona, van Dongen, Solti, & Weidlich, 2018), which expresses the replacement compatibility between two servers. The issue is to ascertain whether a server S_1 , serving a client, can be replaced by another server S_2 such that the client-server relationship enjoyed by the client is not impaired, or whether server S_2 is replacement compatible with server S_1 . Server S_2 must possess at least all the characteristics of server S_1 , therefore being able to take the form of (*conform to*) server S_1 and fulfill the expectations of the client regarding what it expects the server to be. In particular, the schema for request messages in server S_2 cannot include any additional mandatory component, regarding the schema of server S_1 , otherwise it would impose more requirements on the client and the interoperability could break.

Figure 2. Compliance and conformance

The server does not have to know the schema used by the client to generate messages, nor the client needs to know the full set of request messages accepted by the server. In this context, two kinds of schema are considered:

- § **Type schema:** A description of the features of a set of messages, including the definition of each possible feature and whether it is optional or mandatory. This is what typically schema description languages such as XML-Schema provide.
- § **Value schema:** The concrete definition of a specific message, with just the features that it actually has. Each message has its own value schema. This is simply a self-description and, unlike type

schemas, includes no variability (range of structured values). A value schema satisfies an infinite number of type schemas (by considering an infinite number of optional features).

Given that the value schemas of the messages actually sent by clients satisfy the type schema of the server, interoperability is possible, with a lower coupling than by sharing schemas. In semantic terms, compliance means that the set of possible message values sent by a client is a subset of the set of values that satisfy the type schema of the server. Conformance means that the set of values that satisfy the type schema of an alternative server (Figure 2) is a superset of the set of values that satisfy the type schema of the original receiver.

As long as compliance and conformance hold, the server can accept messages from different clients. In addition, a client can start using an alternative server without noticing the difference with respect to the original server.

Figure 3 illustrates both compliance and conformance. A client initially used server S_1 , under a compliance relationship. Then server S_2 , conforming to S_1 , replaced it. The client now complies with server S_2 and can use it as if it were server S_1 .

Figure 3. Illustrating compliance and conformance

The compliance-based interoperability mechanism can be detailed in the following way, for the request message (similar for the response message, with client and server roles reversed):

- § The server publishes a request type schema, which describes the type of request message values that the server can accept.
- § The actual request message, sent by the client, is described by a value schema (specific of this message).
- § When the request message arrives at the server, the message's value schema is validated by checking it for satisfaction of (compliance with) the type schema of the server, in the *compliance checker*. If compliance holds, the request message is one of those that satisfy the server's request type schema and is accepted.
- § The request message's value is *structurally* assigned to the *data template*, which is a data structure that satisfies the server's type schema and includes default values for the components in the type schema that are *optional* (minimum number of occurrences specified as zero). Compliance will fail if the request message does not include at least the minimum number of occurrences specified for each component of data template.
- § Structural assignment involves mapping the request message to the server's request type schema, by assigning the message to the data template, component by component, according to the following basic rules:
 - Components in the message that do not comply with any component in the data template are not assigned and simply ignored.
 - Components in the data template that are also present in the message have their values set to the corresponding message's component values.
 - Optional components in the data template missing from the message have their values set to the corresponding default values (specified in the data template).
 - Structured components are assigned by recursive application of these rules.

After this, the data template is completely populated and ready to be accessed by the server. Each request message populates a new instance of the data template. Note that this mechanism is different from the usual data binding of existing technologies, since the server deals only with its own request message type schema. It does not know the value schema of the request message and there is no need for a data binding stub to deal with it. The important issue is that the mapping between the request message and the data template is done in a universal manner (based on primitive data types and on structuring rules) and does not depend on the schemas used by either the client or the server. As long as compliance holds, the structural assignment rules can be applied. This means that coupling is reduced in comparison to classical schema-sharing technologies.

In conformance between the two servers, server S_2 has all the characteristics of server S_1 (and probably more) and is therefore able to take the form of (conform to) server S_1 and fulfill the expectations of the client. If the schema of server S_2 has additional features, with respect to server S_1 , these must be optional, otherwise it would impose more requirements on the client and the interoperability could be impaired.

By the definition of conformance, a client that complies with a server also complies with another server that conforms to the original server, as shown in Figure 3.

FUTURE RESEARCH DIRECTIONS

Compliance and conformance are basic concepts that can be applied to all domains and abstraction levels of Table 1. Although work exists on its formal treatment in specific areas, such as choreographies, an encompassing and systematic study needs to be conducted to formalize the definition of compliance and conformance.

The coupling problem is also relevant for the interoperability of non-functional aspects, namely in context-aware applications and in those involving the design and management of SLR (Service Level Requirements) with respect to enterprise-class applications and their supply chain interactions. Detailing how compliance and conformance can be applied in these cases requires additional research.

In addition, there is currently no practical implementation of an integration technology based on compliance and conformance. There are several possibilities on how to proceed to a practical implementation, namely:

- § In Web Services, to extend WSDL files with another section (which could be designated Structure), in which component resources and links can be exposed, thereby allowing Web Services to have structure.
- § To allow REST resources to have their own service description (e.g., an extended WADL file), thereby allowing the coexistence of the uniform and non-uniform interface approaches in REST.

CONCLUSION

Application integration is a fundamental problem in distributed information systems and entails two slants, interoperability and coupling. Current integration technologies, namely Web Services (Zimmermann, Tomlinson, & Peuser, 2012) and RESTful APIs (Pautasso, 2014), focus more on the interoperability side of the issue than on coupling. They require sharing of the data schemas by the interacting applications, which leads to more coupling than actually needed. Web Services usually require a link to the schema shared by the client and by the server, whereas RESTful applications usually agree beforehand on a given schema, or media type. If an application changes the schema it uses, the others interacting with it must adapt to these changes in order to maintain the interaction.

Both aspects, interoperability and coupling, need to be dealt with in a balanced way. The fundamental problem of application integration is how to achieve the minimum possible coupling while ensuring the minimum interoperability requirements, so that dependencies between applications that hinder changeability are kept to a minimum and applications are able to effectively interact.

Structural compliance (Czepa, Tran, Zdun, Kim, Weiss, & Ruhsam, 2017) and conformance (Carmona, van Dongen, Solti, & Weidlich, 2018) relax the constraint of having to share message schemas and therefore constitute an improved solution over existing integration technologies. Any two applications can interoperate as long as that share at least the characteristics actually required by interoperability, independently of knowing the rest of the characteristics, thereby minimizing coupling and increasing the number of servers that are compatible with a client, and the number of clients that are compatible with a server.

KEY TERMS AND DEFINITIONS

Client: A role performed by a resource C in an interaction with another S , which involves making a request to S and typically waiting for a response.

Compliance: Asymmetric property between a client C and a server S (C is compliant with S) that indicates that C satisfies all the requirements of S in terms of accepting requests.

Conformance: Asymmetric property between two servers, S_1 and S_2 (S_1 conforms to S_2) that indicates that S_1 fulfills all the expectations of all the clients of S_2 in terms of the effects caused by its requests, which means that S_2 can replace S_1 .

Coupling: A measurement of how much an application is dependent on the interface of another application.

Interoperability: Asymmetric property between a client C and a server S that holds if C is compliant with the set of requests allowed by S and S is conformant with the set of responses expected by C .

Resource: The computer-based implementation of a service.

Server: A role performed by a resource S in an interaction with another C , which involves waiting for a request from C , honoring it and typically sending a response back to C .

Service: The set of operations supported by an application that together define its interface (the set of reactions to messages that the application is able to receive and process) and behavior.

A Survey of Tasks Scheduling Algorithms in Distributed Computing Systems

INTRODUCTION

There are various causes for using DCS. The nature of equipment may involve the utilization of a communication network which connected by some computers: for eg, data created in one site and needed in another site. There are various cases in which only one computer is required, but DCS is very helpful for practical causes. For eg., it may be extra cost-efficient to get the inclined level of performance by applying cluster of numerous low-end computers, in similarity with only high-end computer. DCS has no single point of failure, so it can offer additional reliability than a non-distributed system. DCS may be simple to expand and run than a uni-processor system. DCS have used in a large scale due to several characteristics such as communication, computational speedup, fault tolerance, increased throughput, resource sharing etc.

Tasks scheduling is very important phase in DCS, mainly it is assigning of tasks onto processors as a manner so that some efficiency actions are optimized. An effective tasks scheduling policy avoid too much inter-tasks communication and utilize the precise effectiveness of the processors. It is extremely important step in exploiting the capacity of system and it may be done in two ways: **Dynamic Scheduling** and **Static Scheduling**. The most important plan of tasks scheduling is toward decrease the running cost of a program. The cost can be characterized by time, money or some other measure of resources usage.

In DCS, resources of system can be split by users at different sites through the communication link. However in proper utilization of total computing power of DCS, a fundamental problem arises. It may happen that a certain processor has very few workloads while another processor has more workload at a given time. It is required to distribute total workload of DCS of its overall processors. This evades under use of power and further it decreases response time for deputize at more heavily loaded processor. Generally, the form of computing power sharing with the intention of getting better performance of a DCS by rearranging the workload between the available processors called load balancing. The progress in the presentation of system through redistributing the workload among processors is the main aim of load balancing policies.

The reliability of DCS is probability that system can run the whole application successfully. If system is complex then it is very difficult to system in it's entirely. The logical technique is applied to crumble the entire system into function entities compiled of subsystems and units. Each entity is either operational or failed. The sub-division generates the block diagram of system. Models are prepared to fit the logical arrangement and calculus of probability is applied to figure out reliability of system in terms of sub-division reliabilities. There are two types of reliabilities in DCS: first is processor-related reliability,

DOI: 10.4018/978-1-7998-3479-3.ch018

Table 1. Difference between serial and parallel processing

S. No.	Serial Processing	Parallel Processing
1.	There exist several tasks and processors even although only single task is active on a processor at a given time	More than one task of the program may execute concurrently for various periods during the lifetime of a program
2.	The main concern in a serial processing of programs is variability or non-uniformity of computation requirements and the overhead of communication	The main concern of parallel processing is to reduce the total time of the program by running different parts of the program
3.	The challenge of distributed processing lies in matching requirements against resources without incurring excessive communication overhead	In parallel processing, arranging the order of execution of the various tasks on the processors is a major problem
4.	Generally, serial processing is used for long distance	Generally, parallel processing is used for short distance

for example reliability of resources and reliability of computation; another is the path / link-related reliability, for example reliability of communication paths between allocated processors.

The processing of a program is of two types: serial processing or parallel processing.

Difference between serial processing and parallel processing are given in the following table-1:

Figure 1 and Figure 2 show the execution of tasks on processors in a serial and parallel way respectively. A serial program made up of five tasks is executing on a single processor in Figure 1(a), while the same serial program is executed over a two processors system in Figure 1(b). Processor P2 can execute two tasks (3 and 4) more efficiently but due to transfers of control between tasks over a communication link incur appreciable overhead.

Figure 1. Serial Processing

Figure 2. Parallel Processing

Further the chapter is planned as follows: Section 2 portrays the background of task scheduling techniques. Section 3 covers the application of task scheduling in DCS. Section 4 describes the future research directions. In section 5, conclusion is discussed on the basis of various factors in task scheduling techniques.

BACKGROUND

In this section different approaches for solving tasks scheduling problem with one or more objectives are discussed. These approaches are characterized according to the taxonomy given in the following Figure 3.

Figure 3. Classification of Tasks Scheduling Approach

Exact Approaches

Exact approaches yield optimal solution in a period by limiting the formation of program. Exact approaches are classified into the following approaches:

- Graph Theoretic Approach
- Mathematical Programming Approach
- State Space Search Approach

Graph Theoretic Approach

It is one of the important approaches for optimization in DCS. It uses the graphical method to represents and allocation of tasks onto the processors. Further it may be classified into two techniques: **Network Flow Technique** and **Shortest Path Technique**

- **Network Flow Technique**

A directed graph in which each edge has a capacity and gets a flow is called network flow or transportation network. The total of flow on an edge cannot beat the capacity of the edge. [(Stone, 1977) and (Lee & Shin, 1997)] uses network flow algorithm for tasks scheduling in DCS.

- **Shortest Path Technique**

In shortest path technique, Program chart is changed into assignment chart to apply shortest path technique; it assesses set of processors in assignment chart to select most excellent possible way for scheduling of tasks to the processors. The processors and edges among them are tagged accordingly on method used to get shortest path from source-processor to terminal-processor. [(Bokhari, 1981), (Hui & Chanson, 1997), (Ying, Shakkottai, & Reddy, 2009) and (Meng, Li, Liu, & Ngan, 2012)] used shortest path scheme to solve tasks scheduling problem with purpose of minimization of system cost.

Mathematical Programming Approach

It is used at a large scale for modelling and analyzing several kinds of problems. Initially it converts the tasks scheduling problem into optimization problem and then solve. The following techniques are included in this approach:

- Branch & Bound Technique
- Integer Programming Technique
- Dynamic Programming Technique
- Branch & Bound Technique

It is extremely popular and widely accepted techniques by researchers. [(Kartik & Murthy, 1995), (Kim, Lee, & Lee, 2015), and (Lu, Zhou, Yue, & Chen, 2016)] discussed the Branch & Bound Technique for scheduling the tasks in DCS.

- **Integer Programming Technique**

It is mathematical optimization, in which few or all variables are limited to be an integer. A tasks scheduling model becomes additional noteworthy and sensible when it adds real-time constraints for instance execution, memory limits of each processor, inter-tasks communication, etc. Integer programming is very useful and exhaustive approach for tasks scheduling problems as it is able to replicate real-life conditions of distributed processing and easy in an application. Several researchers worked on tasks scheduling problems with different objective by using this technique. [(Manić, Bahiense, & de Souza, 2009) and (Jabr, Singh, & Pal, 2012)] proposed integer programming formulation for the least failure distribution system reconfiguration problem.

- **Dynamic Programming Technique**

Dynamic programming technique is applied for both mathematical optimization and computer programming. It is an algorithm formation technique which can be utilized when outcome of problem

may be observed as outcome of sequence of result. Various research papers [(Bokhari, 1981),(Ashrafi & Berman, 1992), (Dhakal, Hayat, Pezoa, Yang, & Bader, 2007), (Mishra, Mishra, Mishra, & Tripathi, 2012), (H. Kumar, Chauhan, & Yadav, 2016), (Janati et al., 2017)] use dynamic programming technique to get the result of tasks scheduling problem in DCS.

State Space Search Approach

To make the best use of this approach for tasks scheduling problem, first the problem is switched into a state space search tree and then cost function is defined for leading search. The path defined by the chain of operators which show the ways an initial processor to one of the external processor is the solution path. [(Shen & Tsai, 1985), (Shatz, Wang, & Goto, 1992),(Doğan & Özgüner, 2000) and (Sekhar, Manoj, & Siva Ram Murthy, 2005)] worked on A* algorithm to discover the solution of tasks scheduling problem for the optimization of system cost and system reliability.

Heuristic Approaches

Although an optimal solution of the tasks scheduling problem can be find by using exact approach but generally, it is a NP-hard problem. Therefore finding optimal solution with exact approach to large scale problem is computationally prohibitive. Hence, heuristic approaches play an important task for offering solutions to different kinds of problems. Heuristic approaches provide near to optimal solution for tasks scheduling problem. (Arora & Rana, 1980) used heuristic approaches for tasks scheduling problems in a DCS. Further Heuristic approaches can be characterized into two types: Randomized Optimization Approach and Clustering Approach

Randomized Optimization Approach

It is a probabilistic approach, which applied to discover the solution of tasks scheduling problem. It begins from as an initial solution and searches for the progress in the scheduling by switching and shifting tasks between processors. From this approach, the following techniques are derived to obtain the solution of tasks scheduling problem:

- Genetic Algorithm Technique
- Honey bee Optimization Technique
- Particle Swarm Optimization Technique
- Simulated Annealing Technique
- Genetic Algorithm Technique

It is foundation upon the Darwin's theory of "survival of fittest". It follows the behavior of the reproduction in nature. The main steps of genetic algorithm are reproduction, selection, crossover and mutation. Selection, mutation and crossover and are called genetic operators and used repeatedly until the termination condition is not satisfied. The block diagram of genetic algorithm is given in Figure 4.

[(I. Ahmad, Dhodhi, & Ghafoor, 1995), (Mishra et al., 2012),(Tripathi, 2000), (Hsieh & Hsieh, 2003) and (Yang, Hu, & Guo, 2009), (Omara & Arafa, 2009), (S. G. Ahmad, Liew, Munir, Ang, & Khan, 2016), (H. Kumar, Chauhan, & Yadav, 2019)] proposed genetic algorithm for tasks scheduling in DCS. It is also used for load balancing through the execution face to make use of resources at maximum level.

Figure 4. Block Diagram of Genetic Algorithm

- Honey Bee Mating Optimization Technique**

It is based on meta-heuristic which motivated by the public group of honeybees and their process of reproduction. In this technique, simulated annealing coincides to mating procedure of honeybees; genetic algorithm replicates the breeding process and application based local search replicates the process of nourishing the children and queen bees. [(Abbass & Abbass, 2001), (Fathian, Amiri, & Maroosi, 2007), (Q. M. Kang, He, Song, & Deng, 2010), (Q. Kang & He, 2013) and (Jin, Zhang, & Shao, 2015) build up a hybrid honey bee mating optimization algorithm to finding the solution of tasks scheduling problem with the optimization of system cost.

- Particle Swarm Optimization Technique**

It is a meta-heuristic optimization method and introduced by Kennedy and Eberhart (1995) and induced by the actions of fishes schooling and bird flocking. It has some principle mechanisms such as: particle representation, swarm, experience and stopping criterion. It is very similar to genetic algorithm. In this technique, each swarm of individuals in search space is a candidate result to the optimization problem. Each element shifts in the region of in multi-dimensional search space with dynamically velocity and regulated according to the flying skill of the individuals and its generation. This technique increases the stochastic behavior of the particle and meets quickly to global minima near to optimal solution. It has a great application to solve tasks scheduling problem in DCS. [(Salman, Ahmad, & Al-Madani, 2002), (Yin, Yu, Wang, & Wang, 2006), (Zhang, Chen, Sun, & Yang, 2008), (Q. Kang & He, 2011) and (N. Kumar & Vidyarthi, 2016)] uses particle swarm technique for tasks scheduling in DCS.

- Simulated Annealing Technique** It is a global optimization technique and applied to get the lowest peak in energy land space. It follows the physical conceptions of temperature and power of dynamic system while temperature is launched to randomize the find a solution. Several researchers [(Rutenbar, 1989), (Attiya & Hamam, 2006), (He, Gu, & Zhu, 2010), (Damodaran & Vélez-Gallego, 2012), (Arya & Dhingra, 2015), (X. Liu & Liu, 2016) and (Wu, Wang, Pedrycz, Li, & Wang, 2017)] have used simulated annealing approach to get the solution of tasks scheduling problem in DCS.

2.2.2 Clustering Approach

Mostly research work on heuristic algorithms has dedicated to minimization of inter-tasks communication cost. Clustering approach is one of the heuristic approaches which is applied to decrease the inter-task communication cost by clustering the highly communicated tasks together. Generally, the number of tasks clusters and processors must be equal to reduce the size of program in system so that it could be extremely supportive to get a good quality scheduling. [(Sarje & Sagar, 1991), (Abdelzaher & Shin, 2000), (Lin, Lin, Lin, Hsiung, & Shih, 2013), (Li, Tang, Veeravalli, & Li, 2015), (Y. Liu, Zhang, Li, & Niu, 2017) and (Singh, Gupta, & Jana, 2018), (H. Kumar, Chauhan, & Yadav, 2018)] used clustering approach to solve tasks scheduling problem in DCS.

3. Applications of DCS

DCS has widely used in a lot of fields such as:

- Telephone networks.
- Nuclear Reactor.
- Network files systems.
- Computer networks such as internet.
- Aircraft control system.
- Industrial control system.
- Distributed rendering in computer graphics.
- Wireless sensor networks

FUTURE RESEARCH DIRECTION

Tasks scheduling in DCS is a wide area for research. The effort of categorizing tasks scheduling does not come to a close to end. Several researchers have applied various techniques for solving the tasks scheduling problem such as: genetic algorithm, honey bee mating optimization, particle swarm optimization etc. Use of soft computing techniques such as neural network and various modified soft clustering technique can also be used for tasks scheduling in future. The need for classification and survey of tasks scheduling literature for DCS will remain in the future. A very few research has been carried out on dynamic tasks scheduling and load balancing problems. Therefore, for the ample use of DCS, dynamic tasks scheduling and load balancing are an important issue for further investigation.

CONCLUSION

The classification of tasks scheduling techniques is very demanding due to the huge amount of literature as well as the number of variations of the objectives of the problem. In this chapter we review numerous aspects of the tasks scheduling literature for distributed computing systems, and proposed taxonomy. To confirm the taxonomy, we reviewed various research papers from the scheduling literature, identifying research according to proposed taxonomy. Each of them performs well on the basis of some performance measures. Each of them is compared on the origin of various performance evaluation factors like

computational cost, execution cost, total cost, response time and system reliability etc. This resulted in a study of the latest scheduling research in DCS from variety of features.

KEY TERMS AND DEFINITIONS

Communication Network: Prototype of paths in which information flows in the organization.

Communication Time: In which all users can exchange information instantly or with negligible latency.

Distributed Computing System: Set of processors located at different sites and connected by a communication network.

Execution Time: Time spent by the system executing that task, including the executing running time or system service on its behalf.

Genetic Algorithm: An algorithm that mimics the genetic concepts of natural selection, combination, selection, and inheritance.

Honeybee Mating Optimization: Search algorithm based on swarm approach to optimization.

Load Balancing: Distribution of workloads across multiple computing resources.

Neural Network: Set of algorithms, modelled loosely after the human brain, that is designed to recognize patterns.

Particle Swarm Optimization: Computational method that optimizes a problem by iteratively trying to improve a solution with regard to a given measure of quality.

Response Time: Total amount of time it takes to respond to a request for service.

System Reliability: Describes the ability of a system to function under stated conditions for a given period of time.

Tasks Scheduling: Method by which work is assigned to resources that complete the work.

High-Speed Viterbi Decoder

BACKGROUND

Generically, a communication system includes a channel encoder at the transmitter and a channel decoder at the receiver. Encoding the bit stream to be transmitted reduces the energy per data bit needed to achieve the same bit error rate (BER) over a noisy channel compared to a non-coded transmission. A better channel code needs lower energy to obtain a particular BER.

Convolutional Encoder

Two major classes of binary codes are block codes and convolution codes. In this article, the authors are only concerned with convolution codes (P. Elias, 1955). Convolution codes operate over a continuous bit stream. A convolutional encoder is used to generate the encoded bitstream. A typical implementation consists on a shift register and a set of modulo-2 addition. The content of the shift register defines the state of the encoder (s bits), from which a finite state machine with $m=2^s$ states is obtained. Figure 1 shows an example of a convolution encoder with rate 1/2 (rate 1/ c generates c bits for each input bit) and its state machine.

Figure 1. Convolution encoder with rate 1/2

An alternative way to represent the behavior of the encoder was proposed by Forney (G. D. Forney, Jr., 1967) designated *trellis representation*. A trellis is one of the most convenient ways to visualize the behavior of the decoding algorithms (see Figure 2).

Each node in the trellis represents a state of the FSM. After m time steps, the trellis is full and the branch pattern repeats indefinitely.

Most work on trellis decoding was dedicated to the codes with a rate of $1/r$. This type of codes will provide the simplest trellis decoding since there are only two nodes leaving and entering a state.

Viterbi Algorithm

The Viterbi algorithm (VA) was proposed in 1967 by Andrew Viterbi (Viterbi, 1967). The algorithm decodes convolutional codes with an optimum non-sequential algorithm. Contrary to previous algorithmic solutions whose complexity increases exponentially with the length of the encoded sequence, the computational complexity of the Viterbi algorithm increases linearly with the length of the bit stream. The algorithm has three main steps: (1) branch metric calculation; (2) trellis calculation; and (3) trace-back decoding.

The branch metric, bm , calculation determines the squared Euclidian distance, between the received symbol, r_k , and the expected symbol associated with a branch of the trellis diagram, c_k , that is, $|r_k - c_k|^2$. At every time step, $2 \times m$ branch metrics are calculated since each state has two input branches.

The linear computation complexity of the VA is achieved by discarding unlikely branches in the trellis diagram using the Principle of Optimality (Bellman and Dreyfus, 1962). According to this, whenever two paths of the trellis diagram merge into the same state only the path with the best metric (most likely) must be kept. This path is designated *survivor path*. At each time step, this operation is applied to all paths and m survivor paths are obtained at each time step. Formally, a state metric, $sm(state)$ (see figure 3), is updated as follows:

$$sm(S_a^{t+1}) = \min(S_b^t + bm(S_b^t, S_a^{t+1}), S_c^t + bm(S_c^t, S_a^{t+1})) \quad (1)$$

Figure 3. State metric update

At each time step, the trellis calculation step obtains m decision symbols, one for each surviving branch. These symbols must be stored to help recover the symbols responsible for specific transitions during the traceback decoding step.

The trellis computation stops after a predetermined number of steps or after the decoding of the complete stream. From the m survivor paths, the final step (traceback decoding) starts in the state with the best metric and tracebacks through the path identified by the decision bits until reaching the first state and, consequently, obtain the most likely sequence of symbols.

The higher the number of steps before starting the traceback process, the higher the latency and the memory requirements. To reduce the latency and/or memory requirements the trellis process can be stopped after a pre-defined number of steps by, for example, considering extra bits that terminate the trellis in a defined state. The disadvantage of the method is the overhead associated with the introduction of bits with no information. Fortunately, the VA has one property that allows us to stop the trellis process in the middle of the decoding process and still recover the trellis path. Considering the m survivor paths at a step in the trellis diagram, when traced back, these paths merge into a single path (see Figure 4).

Figure 4. Traceback of survivor paths merging into a single path

Formal estimations of L can be found in the literature (Anderson and Balachandran, 1989). However, in practice, the required value for L is found by simulation.

Viterbi Decoder

The Viterbi decoder implements the Viterbi algorithm with three functional units, one for each of the three steps of the VA (see Figure 5).

Figure 5. Viterbi decoder

The branch metric unit (BMU) calculates the Euclidian distances associated with each branch for each input symbol. The Viterbi algorithm considers, by definition, that the received sequence is “hard”, that is, the decoded bits are either 0 or 1. Instead of hard decision, soft decision can be considered, where soft bits (several bits) represent real numbers. In practice, at least three bits are used to represent the expected and received symbols.

The branch metrics are then accumulated with the state metrics and the survivor paths are chosen. This is implemented with an add-compare-select unit (ACSU), which adds the metrics, compares the

metrics entering a state and selects the best metric. The decisions, d , are stored in a memory and used by the traceback unit (TBU) to recover the symbols associated with the survivor path.

Considering the branch metric unit implementation, the Euclidian distance between a received symbol, r , and the expected symbol associated with a branch of the trellis diagram, c , is $|r-c|^2$ applied to all dimensions, d . Formally,

$$b_m(r - c) = \sum_{n=0}^{d-1} (r_i^2 - 2r_i c_i + c_i^2)$$

In the equation, both squares, r_i^2 and c_i^2 contribute equally to the equation and thus can be neglected. So, the equation simplifies to:

$$b_m(r - c) = -\sum_{n=0}^{d-1} (r_i c_i)$$

The Add-Compare-Select Unit (ACSU) accumulates the branch metrics of each branch along the trellis diagram. At each time step, it must do m (number of states) accumulations. The ACS unit updates the metric, m_x^t , as follows

$$m_x^t = \min \left(\left(m_{y \rightarrow x}^{t-1} + b_{m_{y \rightarrow x}} \right), \left(m_{z \rightarrow x}^{t-1} + b_{m_{z \rightarrow x}} \right) \right)$$

The ACS unit of a state receives the accumulated metrics of the previous states and the associated branch metrics. After the add-compare-select operations the circuit generates an updated accumulated metric of the survivor path and a decision bit.

There are several implementation alternatives for the ACS unit: (1) direct implementation; (2) serial implementation; and (3) parallel implementation.

In the direct implementation, m add-compare select units are used, one for each of the m states. The direct implementation is a straightforward solution for the VD. The area of the design increases with $m=2^s$. Therefore, a new bit in the encoder state corresponds to an area duplication of a direct ACSU implementation. Besides the exponential increase in the arithmetic units of the ACSU there is also the increase in the number of feedback connections of the ACS units. Usually, the performance of the ACS unit is determined by these feedback connections. Many direct implementations of the VD were proposed for different number of states. For example, in (Lin, et al, 2005) a 64-state direct implementation was proposed and in (Chang, Suzuki, and Parhi, 2000) the proposal was a 256-state direct implementation. The solution is expensive in terms of resources but one time-step takes only the time of a single unit to execute.

A serial implementation of the ACS unit uses less than m ACS units. The execution time of a single time-step depends on the number of available ACS units. In case, for example, a single unit is used, than a time-step takes m times the delay of a single ACS unit. The implementation reduces the utilized resources but reduces the performance compared to the direct implementation. The serial implementation, also designated time-multiplexed solution or folding, reduces the number of ACS units of a direct implementation by assigning multiple add-compare-select operations to a single ACS unit (*folding factor*) (Shung, et al., 1993 – part I), (Shung, et al., 1993, – part II). The time-multiplexed implementation

reduces the number of ACS units, but there is an increased design complexity relative to the controller and an increase in the number of registers. Also, the critical path increases due to extra multiplexers to route data to a single unit which reduces the expected linear increase operating frequency considering the folding factor.

When the encoded data is received in a continuous stream of bits, the path metric which is the accumulated value of the branch metrics, may overflow. To avoid overflow, the path metrics must be normalized. A very efficient technique that avoids overflow is the modulo normalization technique (Shung et al., 1992) that automatically normalizes the path metric. In modular arithmetic the metric, m_j , is replaced by the normalized metric

$$\widehat{m}_j = \left(m_j + \frac{C}{2} \right) (\text{mod } C) - \frac{C}{2},$$

where C is the maximum value represented by the number of bits used for defining the path metric. The differences in the survivor metrics remain unchanged using modular arithmetic provided that $\text{diff} \leq \frac{C}{2}$, where diff is the bound of the difference between survivor metrics. Formally, the required number of bits for the state metric is given by:

$$S_{\text{bits}} = \log_2 (2 \times \Delta_{\text{max}})$$

where $\Delta_{\text{max}} = \lambda_{\text{max}} \log_2 m$, λ_{max} = maximum branch metric and m is the number of states. For example, for 64 states, and code rate of 1/3, $\lambda_{\text{max}} = 18$. So, $S_{\text{bits}} = 8$. This normalization is implemented in hardware using a 2's complement adder.

Another simplification rule following the metric calculation using modular arithmetic is the modified compare (Shung et al., 1992). The modified comparison rule applied to two normalized metrics with p bits

$$\widehat{mx} = \left(\overline{mx_{p-1} + mx_{p-2} + \dots + mx_0} \right) \text{ and } \widehat{my} = \left(\overline{my_{p-1} + my_{p-2} + \dots + my_0} \right)$$

is given by:

$$mx_{p-1} \oplus my_{p-1} \oplus y(mx_{p-2} + \dots + mx_0, my_{p-2} + \dots + my_0)$$

where $y(\cdot)$ denotes the unsigned comparison. In general, this comparator is smaller and faster than using a subtractor to implement comparison.

The trace-back unit receives the accumulated metric values of all states, finds the state with the lowest value and returns the path ending in this state, that is, the sequence of bits that best matches the received sequence. A fast approach is to use a tree of comparators having $\log_2 m$ levels, that is, $\frac{m}{2}$ comparators at the first level, $\frac{m}{4}$ at the second, and so on (or $\frac{m}{2}$ shared comparators). After $\log_2 m$ cycles, the state with the lowest metric is identified. The solution is fast but expensive in terms of hardware

resources. An approach with small area is to consider a recursive process where at each iteration the highest value found so far is compared to a next value. This sequential solution takes m cycles to complete, increasing considerably the latency and may become the bottleneck if the ACS step takes less than m cycles. Usually, an efficient solution is to consider a tree of iterative comparators (Véstias et al., 2012).

TECHNIQUES FOR HIGH-SPEED VITERBI DECODING

Several techniques to speed-up Viterbi decoding exist at different levels: bit-level, word-level and algorithmic level.

Bit-Level Optimizations

The lowest level optimizations introduces parallelism at the bit level. These include improved techniques for addition (e.g., carry-save adders) and hardware optimizations and reorganization inside BM and ACS units.

Considering noiseless symbols 0 and 1 of c (see previous section) represented by the symmetrical values -1 and +1, the branch metric unit reduces to add/subtraction of the received values

$$b_m(r - c) = -\sum_{n=0}^{d-1} \pm r_i$$

Therefore, only additions need to be implemented to calculate the branch metrics. The number of operations can be further reduced to half since $b_m = -\overline{b_m}$.

A few bit-level optimizations techniques have also been proposed to improve the performance of the ACS unit. For example, an ACS parallelization technique was proposed in (Véstias & Sarmiento, 2010) to reduce the critical path of the unit. The critical path of the ACS unit includes one adder, one comparator and one multiplexer. To reduce this critical path, the addition in the ACS unit is done in parallel with the comparison.

Word-Level Optimizations

Word-level optimizations merge consecutive transitions of the trellis diagram into a single transition to reduce the number of iterations. To determine the minimal path, transitions are unmerged (Cheng, C. & Parhi, K., 2008).

A lookahead technique of two or more levels is a quite effective parallelization technique (Fettweis, 1989), (Black & Meng, 2002). In a single cycle the technique updates the state metrics of n consecutive steps and thus ideally increases the throughput n times, compared to a direct implementation. However, there is an area penalty proportional to n . To see how the technique works, let's consider a trellis diagram with states with two inputs and two outputs (radix-2) and collapse two steps into a single one producing a radix-4 trellis diagram (four branches entering and leaving each state) (see Figure 6).

Higher radices could be considered. However, as concluded in (Black & Meng, 1992), radix-4 solutions are more area efficient than higher radices. Also, the critical path increases due to the extra operations of the ACS unit and the feedback interconnections. In (Black & Meng, 1992), a full-custom

Figure 6. A radix-2 trellis diagram transformed into a radix-4 trellis

implementation of both radix-2 and radix-4 architectures have shown speed-ups of 1.7, lower than the theoretical 2 times speed-up.

Algorithmic-Level Optimizations

Unbounded throughput using parallelization can be obtained with the minimized method (Fettweis & Meyr, 1991) and the sliding-block decoder (Black & Meng, 1997). Following these techniques, parallel implementations of the VD can be implemented by decomposing the input data into $k \times M$ blocks which can be processed in parallel using k conventional Viterbi decoders. The complexity of the circuit increases linearly with the throughput. However, each block processing requires the initial state metrics to be known and this is only available after the previous block has finished processing. Three techniques have been proposed as a solution to this problem: state initialization (Dunn, 1978), interleaving (Lin & Messerschmitt, 1989) and sliding block (Tzu & Dunham, 1981). The state initialization technique forces the encoder to a known state at the start of each block. This adds complexity to the decoder since it needs block synchronization. The interleaving technique processes independently encoded sequences. However, this approach cannot be used when intersymbol interference is present. The sliding block decoder technique processes independent overlapping blocks simultaneously. To acquire the initial states, two sync blocks are used at the beginning and at the end of the block. The method is based on two main observations. One is that the survivor paths from all possible starting states merge with high probability L iterations back into the trellis. The parameter is the survivor path length (SPL) and is typically $5 \times s = 5 \times \log_2 m$ (Clark & Cain, 1981). The other is that when starting with unknown initial state metrics, the state metrics after K trellis iterations are independent of the initial metrics. The parameter is the synchronization length (SL) and is also typically $5 \times \log_2 m$ (Viterbi & Omura, 1979).

Based on this characteristics, a state at time n can be decoded using only information from the interval $n-K$ to $n-L$. Typically, $K = L$ is considered. The sliding block VD (SBVD) method applies the Viterbi algorithm to the interval $[n - M/2 - L, n + M/2 + L]$ to decode the interval $[n - M/2, n + M/2]$. To guarantee correct initial and final states, the method considers an initial synchronization block (SL)

Figure 7. Sliding block method for Viterbi decoder

and a final trace-back block (SPL) without decoding for each parallel VD (see the behavior of each VD for the SBVD in Figure 7).

With this technique, independent parallel VD can be used to increase the decoding rate (see Figure 8).

Figure 8. Sliding block method for Viterbi decoder

The relative area efficiency is $\frac{M}{M + 2L}$. As M increases the method approaches the ideal efficiency of 1. However, the bigger the value of M, the bigger the latency and more storing resources are needed to save intermediate states. The decoding rate, DR, of an SBVD is:

$$DR = nVD \times \frac{M}{M + 2L} \times drVD$$

where nVD is the number of parallel VD and $drVD$ is the decoding rate of a single VD. The bit error rate of the decoding process of the VD depends on the length of the initial synchronization step, the length of the final trace-back length and of the trace-back decode length. All these parameters are usually found through system simulation.

In (Sun, F. & Zhang, T., 2007) the optimization process considers the elimination of transitions that are bigger than the current minimum reducing the number of operations to be executed.

FUTURE RESEARCH DIRECTIONS

Fast Viterbi decoders are fundamental for high speed applications that may be subject to real-time constraints. Parallel techniques allow any decoding rate just by increasing the number of parallel Viterbi decoders and thus an increase in the area and power consumption.

One of the characteristics of the Viterbi decoder is that of being the most resource-consuming compared to other decoding algorithms, but theoretically it does maximum likelihood decoding. However, there are some obstacles to yield the ideal maximum likelihood due to several factors, including quantization of the input stream and finite trace back length.

A major challenge in the future of the Viterbi decoder is how to achieve high throughput with low power consumption. This is very important for portable devices.

CONCLUSION

The article describes the backgrounds of the Viterbi algorithm as a way to design a Viterbi decoder. The typical architecture of the Viterbi decoder is explained. Several techniques to improve the decoding speed of Viterbi decoders were described and discussed, including bit, word and algorithmic level techniques.

The Viterbi algorithm was proposed in 1967 and since then many Viterbi decoder architectures were proposed. Different design requirements are appearing every day in different technologies and different applications, in particular, mobile devices that require high-speed at low cost and low energy consumption. Designing high-speed Viterbi decoders is therefore an actual topic of research.

KEY TERMS AND DEFINITIONS

Add-Compare-Select Unit (ACSU): A unit that accumulates the branch metrics of each branch along the trellis diagram.

Branch Metric Unit (BMU): A unit to calculate the Euclidian distances associated with each branch of the Trellis diagram for each input symbol.

Convolutional Codes: A type of error correcting code used in telecommunications.

Convolutional Encoder: A module used to generate convolutional codes.

Trace-Back Unit (TBU): A unit of the VD that finds the state with the lowest value and returns the path ending in this state.

Trellis Diagram: A type of graph where nodes represent states and each node is connected to at least one previous node (state) and one next node (state).

Viterbi Algorithm: An algorithm to decode convolutional codes with an optimum non-sequential algorithm. The computational complexity of the Viterbi algorithm increases linearly with the length of the bit stream. The algorithm has three main steps: branch metric calculation; trellis calculation; and traceback decoding.

Viterbi Decoder (VD): An implementation of the Viterbi algorithm consisting of three main functional units, one for each of the three steps of the Viterbi algorithm.

Field-Programmable Gate Array

INTRODUCTION

Field-Programmable Gate Arrays (FPGAs) are integrated circuits whose logic and their interconnections are configurable. These devices are field-programmable, that is, they can be configured by the hardware designer without any intervention of the manufacturer. Most FPGAs can be reprogrammed as many times as we want with a vast variety of digital circuits.

The applicability of FPGAs have changed since they appeared in the mid-1980s. Initially they were very limited in terms of resources and therefore were used to implement glue logic and small sized digital systems. With the advance of the integrated circuit technology, its density has increased dramatically permitting the implementation of a vast set of applications in different areas like consumer, industrial, automotive, high-performance and communications. Some recent FPGA families are system-on-chips (SoC) with one or more microprocessor cores, memory, cache and reconfigurable logic allowing the implementation of complex hardware/software systems in a single programmable device.

FPGAs are now an alternative for ASIC (Application Specific Integrated Circuits). ASIC are the best solutions for implementing digital systems since they offer better performance and lower power consumption at smaller silicon area. The problem is that designing an ASIC is very time-consuming, with high nonrecurring engineering (NRE) costs requiring expensive tools to design and develop. Besides, after fabrication of the final design in ASIC it cannot be modified without creating a new chip.

The cost unit of an ASIC is lower than that of an FPGA but has a much higher NRE cost. Therefore, the ASIC is the best option only for high volume products. This makes FPGAs the chosen device for small to medium scale product deployment. Designing an FPGA is easier, it permits modifications and upgrades of the design, has a faster time-to-market and so the only viable solution for small companies that cannot incur the high NRE costs and expensive design tools.

This article focus on the architecture of FPGAs, including the so called SoC FPGA. It explains the main blocks of the FPGA, how they have evolved along the last decades and the perspectives of next generation FPGAs. It also describes some applicability areas and how its architecture have evolved to adapt to some of these target markets.

BACKGROUND

Field-Programmable Gate Arrays are silicon devices whose fabric hardware can be programmed to implement a particular digital system. The hardware programming capability of FPGAs gives them some advantages over Application Specific Integrated Circuits (ASIC) whose underlying fixed hardware is design to implement a specific digital system. Deploying and maintaining an FPGA-based system is faster and cheaper than implementing the same system in ASIC, since the ship is already made and just

DOI: 10.4018/978-1-7998-3479-3.ch020

have to be configured to implement a specific function. Later, this function can be changed in the field without having to redesign a new chip and can even be reconfigured dynamically while running some other functionality. While is cheaper to design FPGA than an ASIC, the unit cost is higher for an FPGA. Therefore, the average cost of each of these devices depend on the production volume. The average unit cost of an ASIC decreases faster with the production volume than the cost of an FPGA unit. Therefore, there is a threshold from which ASICs are more cost effective.

The programming flexibility of FPGAs comes with a cost in terms of performance and power consumption. A large area of the FPGA (from 80 to 90%) is dedicated to routing and programming resources. It means that only 10-20% of the chip area is available to implement the hardware system. So, compared to an ASIC, a larger FPGA is necessary to implement the same functionality, the performance is worst due to the delay associated with the configurable routing and logic and the higher power consumption includes the power consumption of programming resources.

Any digital system consists of functional blocks, interconnections between these blocks and input/outputs connections between the functional blocks and off-chip circuits. An FPGA consists of programmable logic, interconnect and I/O modules that are tailored to implement a specific digital system.

FPGA Functional Blocks

The granularity of functional blocks determines the flexibility of the FPGA. The smaller the granularity the more flexible it becomes and the FPGA can be more deeply adapted to the required logic system. In the limit, we can use transistors as the basic cells that could then be interconnected to implemented basic logic gates. This approach was followed in (Marple, D., & Cooke, L., 1992) without success mainly because this very fine granularity requires large amounts of interconnections turning the device quite area-inefficient, with large propagation delays and high power consumption associated with the capacitances of the programmable interconnections.

Different granularities were tried in the last decades, from NAND gates (Plessey, 1992), trees of multiplexers (Gamal et al., 1989) and lookup tables (Carter et al., 1986). Today, an FPGA consists of fine-grain configurable circuits of logic, I/O and interconnections arranged in a regular map see Figure 1).

Configurable input/output (I/O) blocks establish the communication of data to and from the system configured in the FPGA. Configurable logic blocks (CLB) implement the functionality of the system and routing switch (SW) provide configurability to the routing resources.

A configurable logic block issues fine-grained configurable logic and memory resources organized in a hierarchical structure (see figure 2).

A configurable logic block (different vendors call different names to these blocks: CLB, LAB – logic array block, etc.) encapsulates fine-grained logic and memory and some specialized configurable circuitry that improves the design of some functions, like arithmetic. One CLB contains one or more cells with dedicated connections between neighbor cells (the designation of these elements are also vendor dependent; e.g. ALM – adaptive logic module and slice).

Logic in FPGAs is implemented with small look-up tables (LUT) which are basically small memories whose content can be changed to implement a specific function. A LUT with k inputs, designated LUT- k , implements any boolean function with k -inputs. Each cell of a CLB contains one or more locally interconnected LUTs and flip-flops. The size of the LUT determines the area and the delay of the circuit according to two trading dimensions. Larger LUTs reduce the number of logic blocks in the critical path, the amount of inter logic routing, which improves performance. However, as we increase the size of the LUT, the internal delay increases and so smaller logic functions mapped to the LUTs have higher delays.

Figure 1. Basic underlying architecture of an FPGA

Since LUTs are implemented as small memories, vendors took advantage of this to increase the configurability and functionality of slices. LUTs can be used not only to implement logic, but also as small distributed memories or in some cases as shift registers. This flexibility permits the implementation of memories and shift registers without using the flip-flops present in a slice which are left for other functionality.

Figure 2. Hierarchical structure of a fine-grained CLB

FPGA Routing

CLB cells are connected to each other to implement larger and more complex logic functions. Interconnections between CLBs and I/O blocks are implemented with a programmable routing network consisting of wires and switches to route data through these wires. To be flexible enough and accommodate large and complex circuits, routing interconnections must be massive and flexible.

The propagation delay of a wire increases with its length. Fortunately, most designs exhibit locality and so fast local and short wires should be more abundant than long wires for a more efficient interconnection network. The network must also consider the special clock and reset lines and distribute them across the FPGA so that clock signals are distributed with low skew and able to keep sequential circuits synchronized.

The architecture of the interconnection network defines the position of the channels in between the sea of logic blocks, the width of channels and how they interconnect to each other. At a more detailed level, it defines the length of wires, its locality, the switching patterns and how they connect to the logic blocks. The global organization of routing architectures can be of two different types: hierarchical (Aggarwal, A. & Lewis, D., 1994) or island-style (Brown, S. D., 1992). Hierarchical routing organizes blocks of the FPGA into clusters. Logic blocks inside a cluster are interconnected with local wires, while interconnecting blocks in different clusters must go through one or more levels of routing. The structure is similar to a tree of connections where the higher the level the more wires are in a channel. The problem with this type of organization is in the design mapping since an unmatched between the routing architecture and the routing requirements of the design forces the underutilization of logic blocks in a cluster. Also, routing between blocks in different clusters incur a large delay penalty. These disadvantages took commercial FPGAs to adopt a different routing architecture where there exists only one flat level of routing channels – island-style routing.

The island-style routing organizes the logic blocks in a two dimensional array surrounded by routing channels (see figure 1 above). A channel has segments of different lengths which are used according to the connection requirements of each logic block. The locality of communications between logic blocks determined that short, local wires are more abundant than long wires in a channel. This routing style has more positive features than hierarchical routing. Logic blocks have direct access to wires of different lengths improving the connection efficiency of designs requiring different routing patterns. Also, the layout of the island-style structure is more regular improving the scalability of the architecture when compared to a design with a hierarchical routing.

The island-style routing architecture also determines how logic blocks connect to the interconnection structure and how channels interconnect to each other (see figure 3).

Each output and input pin of a logic block connects to the channels through input and output channel blocks. Pins of a logic block do not connect to all wires of a channel block (CB). Connections between adjacent channels are made with programmable switches (SW). These modules have configurable connections that implements different connection patterns whose flexibility depends on the adopted design. Extensive studies have analyzed and looked for the best wire segments size (Betz, V. & Rose, J., 1999), the best switch architectures (Masud, M. I. & Wilton, S., 1999) and the best block channels.

The layout of wires and the type of switch also determines the performance of the interconnection network. Pass transistors, multiplexers and buffers are used to implement basic switches where different ratios between the numbers of each of these components determines the fastest routing structure (Betz, V. & Rose, J., 1999).

Figure 3. Low-level structure of the island-style routing network

Input/Output

Input/output cells of FPGAs interface with external components. Many different external devices must interact with circuits inside the FPGA and so input/output cells are also configurable to guarantee enough interface flexibility that broadens the range of devices that can be connected to the FPGA.

The challenge in designing input/output cells is that many I/O standards exist with different voltage levels (e.g., 1.2V, 1.8V, 3.3 V), transmission speeds, signaling, etc. Supporting as much standards as possible gives FPGAs a great interface flexibility but also increases the I/O silicon area and increases pin capacitance with consequences on I/O performance. In general, the choice of which standards to support depends on the target markets of the FPGAs. Even with a limited set of standards, implementing all I/O with support for all interfaces in this set is not area and performance efficient. Instead, FPGA vendors adopted heterogeneous I/O cells with different banks of cells supporting different sets of standards. This reduces the complexity and improves performance while still guaranteeing for most cases the diversity of I/O standards.

Heterogeneity in I/O cells organized in banks of I/O open a design space relative to the number and type of banks. There are FPGAs where the number of I/O is almost constant for all banks (Xilinx, 2005), while others consider a fixed number of banks (Altera, 2005). Recent FPGAs have adopted a hybrid approach with different FPGA devices having a different number of banks and a variable number of pins per bank (Altera, 2006) providing a more balanced solution in terms of area, complexity and performance.

The speed of I/O is another important aspect in the design of the FPGA. Access to high-speed memory and high-speed links require additional and specific circuitry to support high speed communications. Some high speed interfaces require differential signaling that is implemented with two I/O paired together. Support for multi-gigabits interfaces requires specialized modules for data serialization.

Programming Technology

Different technologies are used to store the programming bits of reconfigurable devices. The most well-known and used is SRAM (Static Random Access Memory) (Carter et al., 1986), flash (Guterman et al., 1979) and anti-fuse (Birkner et al., 1992). In the SRAM technology, program memory cells are implemented with SRAM cells, that is, to control select inputs of routing and logic multiplexers and to implement LUTs. SRAM-based programming technology is the preferred among many FPGA providers. SRAM cells can be reprogrammed an infinite number of times, are fast and are implemented with CMOS technology the same used to implement the logic circuitry of the FPGA. Therefore, the fabrication process is the same for the whole FPGA. However, the technology has some drawbacks, including the size (five or six transistors), volatility (external non-volatile memories are required to store the programming file for the FPGA), security (the configuration bitstream must be loaded into the FPGA device from an external memory which increases the risk of being copied. Encryption of the bitstream is used to avoid security problems) and capacitive load of pass transistors that increases with the reduction of integrated circuit technology.

Some of these disadvantages can be addressed using the flash technology. Flash is non-volatile which eliminates the necessity to load the configuration from an external memory. A programmed flash-based FPGA is ready to work as soon as it is powered-up since it does not have to load the configuration. It is also smaller than SRAM since only needs one transistor but requires high voltage buffers to program flash cells, which increases the area. Contrary to SRAM technology, flash cells cannot be reprogrammed an infinite number of times and requires a different fabrication process.

Anti-fuses are structures with high resistance that can be programmed to have a low resistance. However, unlike the two previous technologies, an anti-fuse can be programmed only once. One of the main advantages of this technology is that the connections can be programmed without silicon, only using metal and the memory is non-volatile. However, it requires current sources to program the anti-fuses. Anti-fuses occupy low area compared to SRAM and flash memories. The main problem associated with anti-fuses is that the manufacturing requires a non-CMOS technology. Also, the technology is not scalable to the recent technology sizes, while CMOS is always up to date, and programming cannot be done without removing the device from the board.

The Road of SRAM-based Field-Programmable Gate Arrays

Since they were introduced in 1984, FPGAs have gone a long evolution process dictated by IC technology evolution, architectural evolution looking to improve performance, silicon area utilization and power consumption, and architectural modifications determined by the target applications. In the following sections, we describe the roadmap of evolution of FPGAs driven by these aspects.

Technology Roadmap of FPGAs

The first FPGA device was proposed by Wahlstrom in 1967 (Wahlstrom, S. E., 1967). The device consisted of a regular array of logic cells that could be programmed to implement logic functions and memory interconnected by a configurable network. Configuration bits were stored in SRAM memory cells. While flexible, an SRAM cell is expensive in terms of silicon area and most of the FPGA silicon was devoted SRAM to store the programming bits. This silicon overhead has delayed the introduction of a commercial FPGA until 1984 when Xilinx introduced the first FPGA – XC2064 (Carter et al., 1986).

Since then the evolution of integrated circuit (IC) technology has allowed high density programmable devices where full hardware/software systems can now be implemented.

The first FPGA – XC2064 – had 64 logic blocks, each with two 3-input LUTs and one register. The die area pushed the IC technology to the limits increasing the cost of the device. The programmability was based on SRAM which requires an external non-volatile memory to store the configuration stream. To face these disadvantages, antifuse-based FPGAs eliminate the need of an external memory and reduces the size of programming memory, at the cost of only one-time programmability. Actel 1280 was one of the first FPGA with anti-fuse technology in 1990.

This scenario suffered a turn around with the great evolution of semiconductor technology following Moore's Law. In 1992 the XC4010 FPGA from Xilinx had about 1000 gates and in 1999 this figure raised to about 1 million with the XCV1000 FPGA with a 0.18 μm technology. This large density fabrication technology brought SRAM-based technology back not only because now silicon area was not a problem but also because anti-fuse technology was unable to keep with the CMOS process technology. Using a homogeneous IC technology was necessary for FPGAs to progress at the same pace of IC fabrication processes. Besides, reprogrammability is now an important aspect that permits in-system programmability and system upgrade.

The IC technology keeps its evolution and FPGAs are at the forefront to use them. The 14 nm Tri-Gate process from Intel was used to fabricate the Stratix 10 Family of FPGAs from Intel (Intel, 2019). This constant increase in IC density drove the design decisions of the architecture of FPGAs looking for the best performance and area efficiencies.

Designing FPGAs for Best Efficiency

The baseline structure of an FPGA considers fine-grained homogeneous configurable logic blocks. Fine-grained logic is quite adaptable to a broad set of logic systems but implies a large fabric overhead in terms of programming circuits for logic and routing and a penalty in performance because of programming switches. On the other side, dedicated logic with specific functionality improves performance, area and power consumption but reduces the mapping opportunities, that is, if a target system does not require this functionality then the silicon area of the dedicated logic is wasted. This creates a tradeoff that has been explored by FPGA vendors.

An important design aspect of FPGAs that determines the area efficiency is the size of a LUT. The tradeoff between the size of a LUT and the area efficiency has been extensively studied (Ahmed & Rose, 2000), (Ahmed & Rose, 2004). The first FPGA used a 3-input LUT. With the increase in IC density LUTs have increased to 4-inputs, LUT-4, and are now with 6-inputs, LUT-6. With more silicon area, keeping the size of the LUTs means more routing silicon area. Larger LUTs reduce the number of logic blocks in the critical path, the amount of inter logic routing, improving performance. However, LUTs with larger granularity have higher internal delays increasing the delay of smaller logic functions. FPGA vendors have introduced some programmability to the size of LUTs. For example, a 6-input LUT of a Xilinx FPGA can be configured as two 5-input LUTs with common inputs or one 6-input LUT. The Altera Stratix FPGA uses ALM with 8-input LUTs that can implement one 6-input logic function, two 4-input logic functions, one 5-input and one 3-input functions, or two input functions that share the same logic function and four inputs.

Another architectural approach to improve area efficiency is to consider dedicated circuitry or hardware modules. Dedicated hard modules with a custom functionality implements this functionality more

Figure 4. Heterogeneous architecture of an FPGA with multiple dedicated circuits

efficiently than using fine-grained configurable logic blocks. The disadvantage is that if the applications does not require them then its silicon area is wasted.

Two levels of dedicated circuits exist in modern FPGAs. The lowest is at the level of the configurable logic block where some circuitry is dedicated to improve arithmetic operations (dedicated circuits for carry chain, bit multiplication, XOR gates for addition) and some for memory (shift registers, support for first-in-first-out buffering, RAM and ROM memories). At a higher level, medium-grained blocks independent of the configurable logic blocks exist also in a tiled regular structure mixed with CLBs (see figure 4).

Block RAM (BRAM) first appeared in a commercial FPGA (Altera, 2003). This memory blocks have a fixed memory capacity but the number of address and data bits is configurable. A set of different aspect ratios are available (e.g., a BRAM with 2K bits can be configured as $2K \times 1$, $1K \times 2$, 512×4 , 256×8 , 128×16 , or 64×32). These blocks can be clustered together to obtain larger memories, in some cases without extra fabric logic. Some FPGAs have heterogeneous memory sizes, with a few extra larger memories (e.g. 512 Kbit) targeting applications where large on-chip memory is important.

Another important configurable aspect of BRAMs in modern FPGAs is the number of ports where single or dual ports are available. Dual port memories allow simultaneous read and write operations. Also, some special features are also configurable, like support for FIFO implementations with reduced utilization of fabric logic.

BRAMs are important for those designs with extensive use of on-chip memory. For those with low requirements in terms of memory, BRAMs are wasted and so its silicon area. Improving area efficiency of unused BRAMs has been a topic of research (Wilton, S. J. E., - 2002) by using memory to implement logic.

Medium-grained dedicated computational blocks are also present in FPGAs. A former FPGA considering dedicated computational blocks was the Xilinx Virtex FPGA (Xilinx, 2005). The block is an 18×18 signed multiplier mapped side by side with a BRAM. In some FPGAs (Altera 2006), the multiplier is configurable, that is, one 36×36 multiplier can be separated in eight smaller 9×9 multipliers. These dedicated multipliers were later replaced by DSP (Digital Signal Processing) modules with extra functionalities, like multiply-accumulate, pattern detection and pre-adders.

Some digital systems require a microprocessor. Since an FPGA is hardware programmable, one or more microprocessors can be programmed as any other digital circuit. To improve performance, some FPGAs include a hard microprocessor that can interface with the reconfigurable logic. One of the first approaches of this kind of FPGAs included an embedded processor connected to reconfigurable logic through a bus (Triscend, 2001). One year later, Altera integrated an ARM core in the Apex 20K family of FPGAs (Altera, 2002) and Xilinx introduced the Virtex II Pro family of FPGAs with the IBM PowerPC core embedded in the logic fabric of the FPGA (Xilinx, 2007). Integrating one or more processors in an FPGA opens many issues related to how the processor interfaces with the configurable logic. Initially, the processor was just another dedicated hardware block, but recent FPGAs follow a different approach considering the microprocessor as a central unit of the system and the programmable logic is used to implement accelerators to help the processor running tasks.

This vast heterogeneity of FPGA blocks increases exponentially the design space of FPGAs with many options for the designer. FPGA vendors have reduced this design space by introducing families of FPGAs according to the target applications. When targeting embedded processing, a microprocessor is fundamental, while high-performance computing requires more dedicated arithmetic blocks, digital signal processing requires arithmetic blocks and memory, and complex digital logic systems require more basic configurable logic blocks. Considering these target applications and markets, different families of FPGAs have different ratios of configurable logic blocks and dedicated units.

Recent FPGAs went a step further by integrating in the same device the programmable logic with a complete processing system with dual and quad-core processors, cache, on-chip memory and several more peripherals and interfaces to peripheral outside the FPGA forming a complete SoC (System-on-Chip) on FPGA. Examples of SoC FPGAs are the ZYNQ All Programmable SoC FPGA (Xilinx, 2018) with a 1.0 GHz (highest speed grade) dual-core ARM Cortex-A9 processor embedded within the programmable logic fabric. Arria V FPGA from Altera also includes an 800 MHz dual-core ARM Cortex-A9 MPCore integrated with the programmable logic. The Atmel FPSLIC is another FPGA device that uses a processor in combination with the programmable logic architecture of Atmel.

Application Domains of FPGAs

The evolution of FPGAs was driven not only by the process technology but also by target applications.

The very first expansion of FPGA production was mainly due to the communications market. Vendors of communication equipment use FPGAs for packet processing in switches and routers (Gibb et al., 2008). The communications area was constantly changing with new routing and switching algorithms. ASIC development processes could not keep up with the dynamism of the communications area, like FPGAs could. Bandwidth consumption is doubling every 2-3 years and communication requirements are everywhere from automotive to industrial equipment and consumer electronics. 400 Gbps (Giga bits per second) are here. FPGAs are used in the high-backplane interconnections and inside cellular networks to support 4G and 5G. The consequence was that vendors did customize their FPGAs for best performance

in the communications area with the inclusion of high-speed transceivers, with hundreds of dedicated multiply-accumulate blocks with a configurable pipeline capable to process packets at gigabit speed.

Another potential application for FPGAs is associated with data centers. Power requirements of data centers increase every year. Data center providers are balancing high-performance and power heat. FPGAs can work as accelerators of CPU clusters for a diverse processing tasks like image search, video transcode, image processing, data analytics, etc. (Putnam et al., 2014). FPGAs run many high-performance computing applications with efficient energy consumption with the advantage that can be reconfigured to run new algorithms. Reconfigurable DSPs play an important role to improve energy efficiency of high-performance reconfigurable computing. This aspect is more effective when fixed-point arithmetic can be used instead of floating-point since DSPs are more efficient to implement fixed-point arithmetic. Intel Arria 10 (Intel, 2017) was the first FPGA to include hardened single precision floating-point digital signal processing blocks.

FPGAs can also be used in some IoT (Internet of Things) embedded systems but only when high processing is required for encryption, data processing, etc. Otherwise, microcontroller devices are less expensive and less power hungry. Industrial IoT is another edge application of FPGAs to process motion control, machine-to-machine communication, real-time processing, etc.

Advanced Driver Assistance Systems (ADAS) can also take advantage of FPGAs for real-time analytics (object detection, object recognition and classification, pedestrian detection, among others).

Military and aerospace benefit from the reconfigurability and rapid development of FPGA-based systems to keep up with the very dynamic development of new standards in these areas. In space, the reconfigurability can be used to overcome design faults and new system functionality.

FUTURE RESEARCH DIRECTIONS

Integrated circuit process technology keep improving which increases logic density per chip. Fine-grained FPGAs is probably the most appropriate architecture for bit manipulation. However, the increasing silicon density of FPGAs permits the implementation of large complex systems, many of them operating on words of bits. The migration from bit to word processing moves the granularity of reconfigurable devices towards coarse grain architectures, where the atomic logic units may be arithmetic logic units or other complex structure. Coarse-grain reconfigurable computing is a research and development area with about three decades of existence with early works like PipeRench (Goldstein, et al., 2000), CHESS (Marshall et al., 1999), or RaPiD (Ebeling, 1996) with 16-bit multipliers, memories and arithmetic units. In some cases, the logic blocks are complete microprocessors (Taylor et al., 2002) (Buts et al., 2007).

In spite of all the research investment and development of coarse grain architectures, it is not clear how these architectures will achieve wide adoption. However, one think is clear, the fine-grain architectures of FPGAs may not be able to keep pace with the silicon density increase. New and more efficient coarse grain reconfigurable architectures are expected in the near future.

FPGA architectures will be greatly influenced by top emerging markets. Internet of Things (IoT) and edge computing encompasses a vast list of applications from smart consumer electronic to data analytics analysis in the edge. Future systems must deal with many different interfaces, heterogeneous computing requirements, low power consumption, etc. FPGAs are one possible solution for these new emerging systems. Other application market where FPGAs are already used is the autonomous driving. Several demanding real-time image processing tasks are essential for a complete autonomous driving experience.

Power consumption is a major concern of future FPGAs. Both cloud and edge computing are facing the dark silicon era, where transistors cannot be all powered together due to thermal power constraints. Power gating techniques must be applied not only to logic circuits but also to routing resources.

The rise of artificial intelligence and machine learning both in cloud and edge computing requires fast and heterogeneous architectures with high performance per watt. Xilinx is already planning future FPGA devices to deal with this market. The adaptive compute acceleration platform – ACAP (Xilinx, 2018) combines scalar engines, programmable engines and intelligent engines targeting data centers, 5G wireless and automotive driver assist.

CONCLUSION

The article describes the architecture of field programmable gate array devices, where logic routing and input/output can be configured for any particular digital system. FPGAs started as devices for glue-logic implementation and are now completely autonomous system-on-chip devices.

With the advance of the integrated circuit technology, its density have increased dramatically permitting the implementation of many different applications in different areas like consumer, industrial, automotive, high-performance and communications. Recent system-on-chip FPGA families have one or more microprocessor cores, memory, cache and reconfigurable logic to implement hardware/software systems in a single programmable device.

The reconfigurable logic of an FPGA consists of heterogeneous fine and coarse-grain blocks interconnected in an island-style routing architecture. The type and size of these heterogeneous blocks has being object of intensive research and discussion to find the most appropriate ones and the most appropriate balance.

The architecture of future FPGAs will be determined by energy consumption metrics and by the necessities of emergent markets, like IoT and machine learning.

Therefore, in spite of 35 years of existence, FPGAs are still an actual topic of intense research.

KEY TERMS AND DEFINITIONS

Block RAM (BRAM): A random access memory embedded in FPGAs for data storage. BRAMs can be interconnected to implement larger RAMs.

Coarse-Grained Granularity: Refers to the granular size of reconfigurable architectures consisting of arrays of units reconfigurable at the word level. A typical example is an arithmetic unit.

Configurable Logic Block (CLB): The basic configurable logic resource of an FPGA. CLBs can be interconnected to implement complex logic functions.

Digital Signal Processing Block (DSP): Configurable hard arithmetic blocks in FPGAs for arithmetic operations. DSPs can be interconnected to implement larger arithmetic operations.

Field-Programmable Gate Array (FPGA): An integrated circuit whose hardware can be configured after manufacturing.

Fine-Grained Granularity: Refers to the granular size of the reconfigurable hardware at the bit level. Fine-grained granularity is typically associated to field-programmable gate arrays.

Granularity: Refers to the relative size of the reconfigurable elements in a reconfigurable hardware architecture.

Hierarchical Routing: An interconnection architecture where routing organizes the FPGA in clusters of logic blocks. Neighbor blocks are interconnected with local wires, while logic blocks in different clusters must go through one or more higher levels of routing.

Island-Style Routing: An interconnection architecture where routing organizes the FPGA as a two dimensional flat array surrounded by routing channels.

Look-Up Table (LUT): A small memory used to implement functions in an FPGA.

Reconfigurable Computing (RC): A computing paradigm that uses reconfigurable hardware for computing purposes.

Reconfigurable Hardware: A hardware structure whose logic elements and their interconnections can be reconfigured to implement a particular logic circuit.

Design of a Simple and Low-Cost Calculator in the Laboratory Using FPGA

2

INTRODUCTION

It is a common practice to realize specific operations/algorithms in embedded systems using programmable general-purpose processors. However, an alternative solution to software implementation is the design of application specific dedicated hardware in order to achieve high performance system at relatively low cost. The advancement in VLSI technology makes it attractive for implementation in any application specific task to minimize the size and power requirements which in turn reduce the cost.

In this view, we aim to design a prototype of a simple, low cost calculator in the laboratory which would enable us to perform the basic arithmetic operations like addition, subtraction, multiplication, division along with some logical operations. Though a great amount of work had been done on Arithmetic and Logic Unit (ALU) design (O-Cisneros et al. 2005; William 2006; Xiao et al. 2008; Oztekin et al. 2011; Singh 2014), it is still a challenging task to implement the algorithms successfully in hardware. FPGAs are matrix of configurable logic blocks connected by programmable interconnects and are used to implement desired functionality after manufacturing (Brown et al. 1992; Rose et al. 1993). Due to the programmable nature of FPGAs, they are used in many application fields, such as ASIC prototyping, wireless communications, video/image processing, surveillance, industrial automation, information appliances, home networking & monitoring, residential set top boxes etc. Beside the promising computational platform of FPGAs, parallel nature of computing and overall non recurring costs make them significantly faster for some applications (Rose et al. 1993; Oldfield & Dorf 1995).

The objective of this work is to design an alternative, simple, low power, cost effective calculator in the laboratory. FPGA prototyping of this reusable, dynamic calculator is a reliable way to verify the design in hardware (Lysaght 1993; Oldfield & Dorf 1995; Kalte et al, 2002). Initial step of design is to frame out the simple arithmetic and logical operations and then it would be upgraded for scientific calculations (inclusion of trigonometric operations and logarithmic calculations). In this work, design guideline of simple arithmetic circuits such as adders, subtractors, multiplier, divider and some logical units are studied and assembled to configure the dynamic calculator. The inputs may be applied either

DOI: 10.4018/978-1-7998-3479-3.ch021

by using switches in the FPGA board or a conventional PS/2 keyboard that is connected externally but interfaced to FPGA and the results are displayed on the (2 × 16) paneled LCD screen available on the FPGA board. The design algorithm of this operation is very simple and hardware resource requirement is also minimal. Hence any low-level FPGA hardware is sufficient to implement the design in the laboratory.

Background Architecture of FPGA

Since 1960, there have already been four generations of ICs .viz SSI (small scale integration), MSI (medium scale integration), LSI (large scale integration), and VLSI (very large scale integration). An electronic circuit usually consists of a CPU, ROM, RAM and other peripherals on one board. VLSI is a process of combining thousands of transistors into a single chip occupying a relatively smaller area (<https://electronicsforu.com/resources/learn-electronics/vlsi-developments-ic-fabrication>).

The primary advantages of using VLSI technology are:

- Reducing the size of circuits.
- Reducing the effective cost of the devices.
- Increasing the operating speed of circuits.
- Requirement of less power than discrete components.

Field Programmable Gate Arrays (FPGAs) are semiconductor devices that may be programmed according to specific tasks after manufacturing, while Application Specific Integrated Circuits (ASICs) are manufactured for specific design tasks. There are some specific software to configure FPGA as simple as an AND gate to as complex as the multi-processor (Zhu et al. 2009). The FPGA stores the specific configuration in RAM, which is why the configuration is lost when there is no power connectivity (Lysaght 1993; Oldfield & Dorf 1995). Hence, they must be configured every time the power is on. FPGAs are prefabricated on silicon chips that can be programmed electrically to implement the desired functions. As shown in Fig. 1, FPGA Architecture consists of three major components —

- Configurable Logic Blocks (CLB), which implement logic functions
- Programmable Routing (interconnects), which implements the functions
- I/O blocks, which are used to make off-chip connections

Configurable Logic Blocks: These blocks provide basic computation and storage elements used in digital systems. A basic logic element consists of programmable look-up-tables, a flip-flop, and some fast carry logic to reduce the area and delay cost.

Programmable Routing: The programmable routing establishes a connection between logic blocks and Input/Output blocks to complete a user-defined design unit. It consists of horizontal and vertical routing channels which again containing multiplexers, pass transistors and tri-state buffers. Pass transistors and multiplexers are used in a logic cluster to connect the logic elements.

Programmable I/O Blocks: The programmable I/O pads are used to interface the logic blocks and routing architecture to the external components. The I/O pads and the surrounding logic circuits form the I/O blocks.

Figure 1. General architecture of Xilinx FPGA

Motivation of the Work

With the rising demand for portable, power efficient and reconfigurable design of electronic circuits and systems in the laboratory, we intend to design a calculator using FPGA which is capable of performing simple arithmetic operations as well as the logical operations and it can preserve the facilities for future modifications that might be necessary. For this purpose we will need to design the arithmetic and logic unit first, followed by the sub modules like multiplexer, binary to BCD converter, interfacing module for LCD display each of which has a definite function and the combined operations of these units will finally make our attempt to use the FPGA as a prototype of dynamic calculator successful.

In this work, the software that is used is *Xilinx ISE 14.2* and the language for designing each of the sub modules is *VHDL*, a hardware description language used in electronic design (Bhasker 1999; IEEE stand. Manual 1993; Perry 2002).

Proposed Architecture

To begin with the initial design of dynamic calculator using FPGA, we need to describe the overall architecture of the calculator as shown in Figure 2. –

According to the block diagram of Figure 2, operations of the proposed ALU architecture can be described as follows.

Whenever the data inputs $a(a_3 a_2 a_1 a_0)$ and $b(b_3 b_2 b_1 b_0)$ are applied by the user and the operations are specified by the *selection lines* of 8×1 MUX, the output of that particular operation will be computed and finally displayed on the LCD screen.

In the proposed architecture, the choice of arithmetic/logical operations is made by the combinations of select lines $(s_2 s_1 s_0)$ of MUX and hence the variation (000 to 010) is restricted for arithmetic operations and the rest of the combinations are considered for different logical operations. Moreover, the output

Figure 2. Block Diagram of the proposed ALU and LCD interfacing architecture

of arithmetic operations need binary to BCD conversion to generate the decimal equivalent value and then corresponding ASCII codes of LCD screen are dynamically produced by the 8-bit parallel adders. However, the results of logical operations have no need for BCD conversion and thus they are directly pipelined to 8-bit parallel adders for generation of ASCII codes.

In the following section, we have described three fundamental sub-modules of the proposed architecture and their functionalities in details.

- Arithmetic Unit (AU):** It is the very fundamental building block of a calculator and performs the following basic arithmetic operations on the operands provided by the user.
 - DIV**– It is a division unit which will divide an 8-bit numerator by a 4-bit denominator to generate a 4-bit quotient and a 3-bit remainder.
 - MULT** – It is a multiplier unit which will multiply a 4-bit multiplicand and a 4-bit multiplier and will generate a product of 8 bits.
 - ADD/SUB** – It is an adder/subtractor unit which will either add or subtract according to the mode value. Operands are two binary numbers each of 4 bits and finally result will be generated in the signed data format.
- Logic unit (LU):** It is another fundamental building block of the calculator and our proposed architecture consists of all basic logical operations as follows -
 - AND** – It is the first logical unit which will perform the AND operation between two binary numbers $a(a_3 a_2 a_1 a_0)$ and $b(b_3 b_2 b_1 b_0)$.

- **OR** – It is the second logical unit which will perform the OR operation between two binary numbers $a(a_3 a_2 a_1 a_0)$ and $b(b_3 b_2 b_1 b_0)$.
- **NOT** – It is the third logical unit which will perform the inversion/negation operation on any 4-bit binary number.
- **XOR** – It is the fourth logical unit which will perform the XOR operation between two binary numbers $a(a_3 a_2 a_1 a_0)$ and $b(b_3 b_2 b_1 b_0)$.
- **NAND** – It is the fifth logical unit which will perform the NAND operation between two binary numbers $a(a_3 a_2 a_1 a_0)$ and $b(b_3 b_2 b_1 b_0)$.
- **Additional Sub-modules:** Few additional building blocks are required to represent the desired output of the prototype in the LCD display panel of FPGA board.
 - A **Multiplexer** unit is used to decide which of the eight operations will be computed when the inputs are applied.
 - The output of the multiplexer will either go to the **Binary to BCD converter** or directly propagate to the **8-bit parallel adder** unit depending on the **select line combination** of the multiplexer. Binary to BCD conversion is required for generating the corresponding BCD form of the binary outputs of arithmetic operations whereas the results of logical operations are directly pipelined to next stages, since there is no need for BCD conversion in those cases.
 - The output of BCD converter/direct results of logical operations will propagate to the inputs of the **8-bit parallel adder** circuits in order to generate the ASCII codes of LCD panel for displaying the results. In this architecture, each of the parallel adder is used to display **single digit** on the LCD screen. Since the ASCII codes for the numerical digits of LCD panel follows a particular pattern like - (0 @30H, 1@31H, 2@32H, 3@33H, 4@34H, 5@35H, 6@36H, 7@37H, 8@38H, 9@39H), one of the input of each 8-bit parallel adder may be kept fixed at 30H (00110000) whereas the other input will remain variable. Therefore, every time the parallel adder will add the variable input with 30H (00110000) to generate the required ASCII codes.
 - The outputs of all the parallel adders will then be interfaced to the LCD module of FPGA board by establishing the proper control signals of controller unit.

In this way we may assemble the individual blocks to display the results on the LCD screen. Further modifications in the design block can be made to upgrade the calculator for more versatile uses. We have described the detailed architecture and functionality of each of the blocks in the following sections.

4.1 Adder/Subtractor: It is a fundamental building block of an arithmetic unit in dynamic calculator. The operations of the proposed ripple carry adder for adding/subtracting two signed binary number is described in the following sections.

Working Principle: As shown in Figure 3, let us assume one of the 4-bit numbers to be $a(a_3 a_2 a_1 a_0)$ and the other be $b(b_3 b_2 b_1 b_0)$. There are 2 separate block of adder circuit each of which consists of a set of 4 full adders. Also there are 2 sets of XOR gates that remain associated with the 2 adder blocks. The mode signal M decides whether the operation to be executed is Addition or Subtraction. If $M=0$, addition will be performed on the 2 inputs and if $M=1$ then subtraction will be performed on the same inputs. The 4-bit sum of the 1st adder block is assumed to be $s'(s'_3 s'_2 s'_1 s'_0)$ and the 2nd adder block as $s(s_3 s_2 s_1 s_0)$.

The algorithmic steps for addition operation (Ray-Chaudhuri 2009; Lewin 1974) are given below:

- In the first block of the circuit one of the inputs a ($a_3 a_2 a_1 a_0$) enters the full adders directly whereas the other input b ($b_3 b_2 b_1 b_0$) enters a set of four 2 input XOR gates. The mode signal M acts as the 2nd input for each of the XOR gates.
- The output of the XOR gates remain same as the input when $M=0$ i.e. during addition. Therefore b enters the 1st adder block unchanged.
- The input carry C_{in} is same as M for addition.
- In each of the full adder of the 1st block a_i gets added to b_i and the intermediate carry passes on until the output carry C_{out} is obtained.
- C_{out} enters another XOR gate named as XI along with M and the final output carry is generated which remains same as C_{out} since $M=0$.
- The **SUM** is the output of the 1st adder block i.e. s' ($s'_3 s'_2 s'_1 s'_0$).

- In the first block of the circuit one of the inputs a ($a_3 a_2 a_1 a_0$) enters the full adders directly whereas the other input b ($b_3 b_2 b_1 b_0$) enters into a set of four number of 2 input XOR gates. The mode signal M acts as the 2nd input for each of the XOR gates.
- Since $M = 1$ during subtraction, the XOR gates generate the 1's complement of the input b and when this is added to $C_{in} = 1$ gives the 2's complement of b . This is added to a in the first block.
- Now, If $a > b$ then the difference is generated by simple addition operation as described in the previous section. If $a < b$ then the following steps have to be computed.
 $\emptyset$ M enters an XOR gate named $X1$ along with C_{out} of the 1st block as well as an AND gate named $A1$. The other input of $A1$ is the output of $X1$. Together they generate the sign bit as the output of $A1$.

- Ø In the 2nd block of the circuit the sum bits from the previous block, $s'(s_3' s_2' s_1' s_0')$ enter as one of the inputs of another set of four XOR gates. The other input of the 2 input XOR gates is the sign bit which is 1 if $a < b$.
- Ø This generates the 1's complement of the inputs which is further added to C_{in} to generate the 2's complement. $C_{in} = 1$ since it is same as the output of AI .
- Ø The 2's complement of $s'(s_3' s_2' s_1' s_0')$ is added to $a(a_3 a_2 a_1 a_0)$ which has been kept 0000 to produce the final output $s(s_3 s_2 s_1 s_0)$. This is the **difference** of a and b .

4.2 Multiplier: Multiplier is a widely used important arithmetic unit. Figure 4 describes the multiplication operation of two binary coded positive integer numbers. This is also the core unit for signed binary multiplication.

Figure 4. Block diagram of a Multiplier circuit

Working Principle: As shown in Figure 4, let us assume that the multiplier is $a(a_3 a_2 a_1 a_0)$ and the multiplicand is $b(b_3 b_2 b_1 b_0)$. Also $b_p = 0000b_3 b_2 b_1 b_0$ and initially the product is $p = 00000000$. We have considered a variable p_v which is the sum of p_v and b_p such that,

$$p_v = p_v + b_p \quad (1)$$

The algorithmic steps of the proposed multiplier (Ray-Chaudhuri 2009; Shirriff 2013) are given below:

- Since the multiplicand and the multiplier are of 4 bits so shifting will take place *thrice* and addition will take place *four* times.
- Initially $p_v = p_v + b_p = 0000b_3 b_2 b_1 b_0$. This is done by the first adder circuit symbolized as '+' as shown in the figure.
- The content of b_p is shifted left by 1 bit by the shifting block 'shl'. Now $b_p = 000b_3 b_2 b_1 b_0$.
- The output of the first adder i.e, the content of p_v enters into the 2nd adder circuit by a 2:1 multiplexer if its select input $a(0)=1$, otherwise the previous value of p_v will go through the multiplexer directly.
- The output of the shifting block i.e, the current content of b_p also enters the 2nd adder circuit.

- Now b_p gets added to the current value of p_v .
- Once again b_p gets shifted by 1 bit to the left by 2nd shifting block 'shl'. Now $b_p = 00b_3b_2b_1b_000$.
- If $a(1) = 1$ the output of the adder moves on to the 3rd adder circuit via a 2:1 multiplexer whose select input is $a(1)$, otherwise once again the previous value of p_v will pass on to the next adder.
- The shifted contents of b_p enters into the 3rd adder circuit as its 2nd input. After addition the contents of p_v gets changed.
- Once again the contents of b_p get shifted by the 3rd shifting block 'shl' so that $b_p = 0b_3b_2b_1b_0000$.
- If $a(2) = 0$ the previous value of p_v passes on directly to the 4th and last adder without any change, otherwise the current value of p_v will move on to the last adder via a 2:1 multiplexer whose select input is $a(2)$.
- Ultimately either the output of the 4th adder circuit or the previous content of p_v will be obtained as the final output which is the PRODUCT depending upon whether the select input of the 4th multiplexer $a(3) = 1$ or $a(3) = 0$.

4.3 Divider: Division is also an important arithmetic operation in the design of dynamic calculator. Figure 5 describes the division operation of two unsigned binary numbers.

Working Principle: Let us consider the numerator to be a 8-bit number (n) and the denominator to be a 4-bit number (d). As shown in the diagram, the numerator has been divided into two parts, n_1 and n_2 . n_1 is a 5-bit number that consists of the 4 bits from the MSB with a 0 inserted at the MSB position and n_2 is a 4 bit number which consists of the remaining bits of the numerator upto the LSB. d is also made a 5 bit number by inserting a 0 at its MSB position. This is done to keep n_1 and d of equal bits. The contents of n_1 and n_2 are shifted left by 1 bit, and if $n_1 > d$ then

$$n_1 = n_1 - d ; n_2(0) = 1 \quad (2)$$

Also we have a provision of displaying the word 'ERROR' if the denominator value is 0.

Figure 5. Block diagram of a Division circuit

The algorithmic steps of the divider unit (Sites 1974; Srinivasan, 1994) are given below:

- The contents of n_1 and n_2 are shifted left by 1 bit and as a result 0 enters as LSB of n_2 .
- If $n_1 > d$ then $n_1 = n_1 - d$ and $n_2(0) = 1$. If $n_1 < d$ then n_1 and n_2 remain unchanged.
- The process of shifting gets repeated thrice. Everytime either $n_1 = n_1 - d$ or both n_1 and n_2 remain unaltered depending upon whether $n_1 > d$ or $n_1 < d$.
- After the 4th and last shift n_2 holds the **quotient** and n_1 holds the **remainder**.

4.4 AND/OR/XOR/NAND: These are few fundamental bitwise logical operations which are used as the fundamental building blocks of digital logic circuits (Katz 1994; Lala 1996).

Working Principle: The above logic unit takes two inputs as $a(a_3 a_2 a_1 a_0)$ and $b(b_3 b_2 b_1 b_0)$ and then performs 4-bit AND/OR/XOR/NAND operations for producing 4-bit output $r(r_3 r_2 r_1 r_0)$.

4.5 Inversion: A logic inverter or NOT gate performs a basic logical operation which inverts its binary input (Lala 1996; Enderton 2001).

Figure 6 Show the pictorial presentation of 4-bit logical AND/OR/XOR/NAND and Inversion unit.

Working Principle: As shown in Figure 6, the above inverter block performs 4-bit inversion operation on input $a(a_3 a_2 a_1 a_0)$ and produces a 4-bit output $r(r_3 r_2 r_1 r_0)$.

Figure 6. Pictorial illustration of 4-bit logical AND/OR/XOR/NAND as well as Inverter Block

4.6 8:1 MULTIPLEXER: Multiplexer is a circuit arrangement that selects one of several inputs and let it propagate to the output, hence it is also known as data selector (Ray-Chaudhuri 2009). In our work, 8×1 MUX is designed in order to select among three arithmetic and five logical operations. Three select line combinations determine which operation is to be performed when the data inputs are applied by the user. Accordingly the result of any one of the said operation is sent by the MUX to the following section of the module.

The algorithmic steps of 8×1 MUX are given below:

- When selection-line $(S_2 S_1 S_0) = 000$, the output of **Division** operation will be selected and the quotient will propagate through the MUX whereas the remainder will enter an 8 bit parallel adder which will be discussed in the following part of the report.
- When selection-line $(S_2 S_1 S_0) = 001$, the output of **Multiplication** operation will be selected and the product will propagate through the MUX to its output.
- When selection-line $(S_2 S_1 S_0) = 010$, the output of **Add/Sub** operation will be selected and the Sum/Difference will propagate through the MUX to its output.

- When selection-line $(S_2 S_1 S_0) = 011$, the output of the **AND** gates will propagate through the MUX to its output.
- When selection-line $(S_2 S_1 S_0) = 100$, the output of the **OR** gates will propagate through the MUX to its output.
- When selection-line $(S_2 S_1 S_0) = 101$, the output of the **NOT** gates will propagate through the MUX to its output.
- When selection-line $(S_2 S_1 S_0) = 110$, the output of the **XOR** gates will propagate through the MUX to its output.
- When selection-line $(S_2 S_1 S_0) = 111$, the output of the **NAND** gates will propagate through the MUX to its output.

The output of the 8×1 MUX either enters as the input of the Binary-to-BCD converter which again converts 8-bit binary result to its corresponding BCD having a maximum of 10 bits or directly pipelined to 8-bit parallel adders depending upon the value of select lines of the MUX.

4.7 Binary to BCD Converter: A binary to BCD converter will convert an 8 bit binary input to its BCD equivalent. For this conversion the method of Shifting and Adding is implemented with some intermediate corrections made during this process (Ray-Chaudhuri 2009; Lewin 1974). The corrections are required due to two reasons:

- (a) Any 4 bit group exceeding 1001 upto 1111 does not represent correct BCD form. This needs a correction when it occurs within a decade due to the left shift.
- (b) The second correction is needed when a bit from the MSB position of a decade is shifted to the LSB position of the next higher decade adjacent to it

All the necessary corrections take place automatically if 0011(=3) is added to the decade which contain a number greater than 0100(=4). The value of any decade may exceed 0100 just after 3 shifts or at the end of 4 shifts. The following algorithm is called “**Add and Shift Algorithm**”.

Figure 7 describes the block diagram of an 8-bit binary to BCD converter.

The algorithmic steps of binary to BCD converter are given below:

- i) Place the binary number outside and to the right of the spaces of decade-0.
- ii) Shift left one bit at a time until the decade value becomes greater than 4 (0100).
- iii) When the decade value is found to be greater than 0100, add 0011 to it and shift left immediately.
- iv) Repeat step (iii) until the LSB of the given binary number has been shifted into the least significant position of decade-0.
- v) The process stops after the last shift and the content of the decade is the required BCD.

4.8 8-BIT PARALLEL ADDER: An 8-bit parallel adder is used to generate each of the ASCII codes corresponding to its input. Once the 8-bit binary result of any one of the arithmetic or logical operation is converted to its BCD format, it is sent to the parallel adder so that it can produce an 8-bit ASCII code for each decimal digit which is to be displayed on the LCD screen. Figure 8 shows the conventional diagram of an 8-bit parallel adder. Since we chose to display the results in the LCD screen by using 3 digits, we need to implement 3 parallel adder circuits in order to generate the ASCII codes of the 3 digits separately.

The algorithmic steps of the proposed 8-bit parallel adder are given below:

Figure 7. Block diagram of Binary to BCD converter

Figure 8. 8 bit parallel adder

- The 8-bit binary parallel adder has two inputs, a ($a_7 a_6 a_5 a_4 a_3 a_2 a_1 a_0$) and b ($b_7 b_6 b_5 b_4 b_3 b_2 b_1 b_0$). The block consists of 8 full adder components. Each full adder adds two input bits along with the carry bit which is forwarded through the carry output of the previous full adder.
- Since in the LCD board, ASCII codes of the numerical digits of Xilinx Spartan-3E FPGA board are: ['0' -- 30H ; '1' -- 31H ; '2' -- 32H ; '3' -- 33H ; '4' -- 34H ; '5' -- 35H ; '6' -- 36H ; '7' -- 37H ; '8' -- 38H ; '9' -- 39H]; the input ' b ' is kept fixed at 30H (00110000) whereas the input ' a ' remains variable. Therefore every time each parallel adder adds the input ' a ' with 30H to generate the required ASCII codes for displaying the results (Xilinx User Guide, 2016; VHDL Designer's Guide).

4.9 LCD Interfacing for Display: A liquid crystal display or LCD draws its definition from its name itself. It is the combination of two states of matter, the solid and the liquid. LCD uses a liquid crystal to produce a visible image. Liquid crystal displays are super-thin technology display screen that are generally used in laptop computer screen, TVs, mobile phones, portable video games and also in FPGA board as shown in Figure 9. LCD's technologies allow displays to be much thinner way in compare to cathode ray tube technology. Proper interfacing procedure of LCD will help to display the output results into (2 × 16) panel as shown in Figure 9.

Figure 9. (i) (2 × 16) panel LCD display; (ii) Pin Configurations

Pin Configurations and the connections between LCD screen and FPGA chip for interfacing are described in detail in Table 1. LCD panel has 8-bit bidirectional data bus interface with some control lines such as Enable signal (E), Register Select (RS) and Read/Write signal (R/W) (Xilinx User Guide, 2016; web link of LCD interfacing tutorials)

The operations of three control signals are given below:

- The *Register Select* control line enables the kit to identify the input as either a Command (to set the cursor, to introduce blank spaces etc.) or a Data (the characters that are to be displayed). $RS = 1$ implies that input is data and $RS = 0$ implies that input is a command.
- The *Read/Write* control enables the kit to either perform read operation or write operation. ($R/W = 1$ implies read operation and $R/W = 0$ implies write operation)
- If the *Enable* input is high, i.e. $E = 1$, then only the data gets latched to the data bus.

Hence by assembling all these modules, we have attempted to design the prototype of a simple calculator that computes and displays the results of the above mentioned arithmetic/logical operations on the LCD screen of the FPGA board.

Table 1. Configurations of LCD board

Pin No	Function	Name
1	Ground (0V)	Ground
2	Supply voltage; 5V (4.7V – 5.3V)	V _{cc}
3	Contrast adjustment; through a variable resistor	V _{EE}
4	Selects command register when low; and data register when high	Register Select
5	Low to write to the register; High to read from the register	Read/write
6	Sends data to data pins when a high to low pulse is given	Enable
7	8-bit data pins	DB0
8		DB1
9		DB2
10		DB3
11		DB4
12		DB5
13		DB6
14		DB7
15	Backlight V _{CC} (5V)	Led+
16	Backlight Ground (0V)	Led-

Experimental Results

In the proposed architecture of dynamic calculator, we are applying the inputs with the switches available on the Spartan-3E series of FPGA board. However, there are 16 switches assigned for the inputs, among which three switches are assigned for three select lines of 8×1 MUX and one is for Mode selection of ADD/SUB unit in our design, hence the number of inputs that can be applied as data inputs a and b , gets restricted to 12. Hence with these 12 number of available input switches, four bit data operations are considered in this proposed architecture such as $a(a_3 a_2 a_1 a_0)$ and $b(b_3 b_2 b_1 b_0)$. The output results computed by the calculator are displayed in the (2 × 16) panel LCD screen of the FPGA board.

In the following sections, experimental results of some arithmetic and logical operations are shown with descriptions.

- (i) Result of Addition: When the MUX is selected for addition operation ($S_2 S_1 S_0 = 010$, and $M=0$), if we provide the inputs as –

$$a(a_3 a_2 a_1 a_0) = \mathbf{0111} \text{ (decimal equivalent 7),}$$

$$b(b_3 b_2 b_1 b_0) = \mathbf{0100} \text{ (decimal equivalent 4),}$$

Output result will be **1011** (decimal equivalent **11**), which is shown in the LCD screen of Figure 10.

Figure 10. Addition Result

- (ii) Subtraction results: When the MUX is selected for subtraction operation ($S_2S_1S_0 = 010$, and $M=1$), if we provide the inputs as –

$$a (a_3 a_2 a_1 a_0) = \mathbf{0010} \text{ (decimal equivalent 2),}$$

$$b (b_3 b_2 b_1 b_0) = \mathbf{0101} \text{ (decimal equivalent 5),}$$

Output result will be **1011**(decimal equivalent **-3**), which is shown in the LCD screen of Figure 11.

Figure 11. Subtraction Result

- (iii) Multiplication result: When the MUX is selected for multiplication operation ($S_2S_1S_0 = 001$), if we provide the inputs as –

$$a(a_3a_2a_1a_0) = \mathbf{1100} \text{ (decimal equivalent 12),}$$

$$b(b_3b_2b_1b_0) = \mathbf{0011} \text{ (decimal equivalent 3),}$$

Output result will be **100100** (decimal equivalent **36**), which is shown in the LCD screen of Figure 12.

Figure 12. Multiplication Result

- (iv) Division results: When the MUX is selected for division operation ($S_2S_1S_0 = 000$), if we provide the inputs as –

$$a(a_3a_2a_1a_0) = \mathbf{0111} \text{ (decimal equivalent 7),}$$

$$b(b_3b_2b_1b_0) = \mathbf{0100} \text{ (decimal equivalent 4),}$$

The quotient will be **0001**(decimal equivalent **1**); remainder will be **0011** (decimal equivalent **3**); which are shown in the LCD screen of Figure 13.

Again for another division operation, if we provide the inputs as –

$$a(a_3a_2a_1a_0) = \mathbf{0001} \text{ (decimal equivalent 1),}$$

$$b(b_3b_2b_1b_0) = \mathbf{0000} \text{ (decimal equivalent 0),}$$

The output result will be “**Error**”, which is shown in the LCD screen of Figure 14.

Figure 14. Division Result

Discussions

In this work, we have attempted to provide a sample overview of FPGA prototyping in the laboratory setup. Since the proposed architecture of calculator computes only some simple arithmetic and logical operations, this may be implemented in any low-level starter kit of FPGA. Presently the proposed architecture utilizes only 7% of CLB slices and 19% of I/O resources of Spartan-3E FPGA board and the design is optimized for speed.

In this proposed architecture, due to the availability of restricted number of input switches, data operations are also bounded by 4-bits. This restriction/drawback may be overcome by interfacing the standard PS-2 keyboard with the FPGA kit and then the architecture will be more flexible for general purpose

use. Moreover, another major drawback of this ALU prototype is computation of only unsigned binary numbers for arithmetic operations which will also be upgraded to both signed and unsigned operations for more versatile use.

Moreover, in this prototype of ALU, we have designed a ripple carry adder for simplicity which can be replaced by carry-look ahead approach for achieving the better speed of computation. A carry-look ahead adder (<https://www.electronicshub.org/carry-look-ahead-adder/>) is a fast parallel adder as it reduces the propagation delay by more complex hardware. It is designed by transforming the ripple-carry adder circuit such that the carry logic of the adder is changed into two-level logic and the circuit at any stage does not have to wait for the generation of carry-bit from the previous stage. Hence, the carry bit can be evaluated at any instant of time.

FUTURE DIRECTIONS

In this study, we only focused on the design and implementation of simple non-scientific arithmetic operations in a low cost manner. A complete design cycle from feeding of input data for any of four basic arithmetic operations to visualization of results in conventional decimal form is presented in this work. Design of this prototype is very easy to understand for the trainee level and it is the main strength of the present work.

All other scientific calculations such as trigonometric, logarithmic and power-law computations may be achieved by exploiting the CORDIC algorithm (<https://www.allaboutcircuits.com/technical-articles/an-introduction-to-the-cordic-algorithm/>). CORDIC is a hardware-efficient iterative method which uses rotations of input vectors by a scaling factor to calculate a wide range of elementary functions. The list of the functions that can be calculated from this rotation is relatively long such as arc-tan, arc-sin, arc-cos, hyperbolic and logarithmic functions, polar to rectangular transform, Cartesian to polar transform etc. Moreover, multiplication and division operations can also be obtained from the variants of rotation.

Furthermore, the prototype will take a more sophisticated look if some provision might be kept for simple mathematical equation solving capability in the architecture.

KEY TERMS AND DEFINITIONS

8×1 MUX: Multiplexer with 8 input data-line and single output terminal.

ALU: Arithmetic and logic unit.

ASCII Codes: American standard code for information interchange.

ASIC: Application-specific integrated circuit.

BCD Conversion: Binary coded decimal conversion.

CPU: Central processing unit.

FPGA: Field programmable gate array.

I/O Block: Input/output block.

LCD: Liquid crystal display.

MSB/LSB: Most significant bit/least significant bit.

RAM: Random access memory.

ROM: Read only memory.

VHDL: Very high-speed integrated circuit hardware description language.

VLSI: Very large-scale integration.

XOR Gates: Exclusive-OR gate.

Modeling of Uncertain Nonlinear System With Z-Numbers

INTRODUCTION

Interpolation technique is extensively implemented in order to function estimation (Boffi & Gastaldi, 2006; Jafarian et al., 2016; Mastlylo, 2010). In (Schroeder et al., 1991) a systolic algorithm in order to interpolate as well as evaluate of polynomials by utilizing a linear array of processors is proposed. Two-dimensional polynomial interpolation is described in (Zoli, 2008). In (Neidinger, 2009) a multivariable interpolation method is proposed. In (Olver, 2006), the multivariate Vandermode matrix is implemented. Recently, Smooth function estimation is extensively used (Szabados & Vertesi 1990; Tikhomirov, 1990) which leads a model by using Lagrange interpolating polynomials at the points of product grids (Barthelmann et al., 2000; Xiu & Hesthaven, 2005). However, if there are uncertainties in the interpolation points, none of these techniques will work properly.

The fuzzy equation is taken to be the general form of the fuzzy polynomial. The concept of fuzzy modeling is based on finding the fuzzy coefficients of the fuzzy equation. Various methods have been developed (Goetschel & Voxman, 1986; Kajani et al., 2005; Mamdani, 1976; Mazandarani & Kamyad, 2013; Salahshour et al., 2012; Takagi & Sugeno, 1985; Wang & liu, 2011; Jafari & Yu, 2015a, 2015b, 2015c, 2015d, 2017a; Jafari et al, 2019a, 2016; Razvarz & Jafari, 2017a, 2017b; Razvarz et al., 2017, 2018). In (Friedman et al., 1998) a general fuzzy linear system is studied utilizing the embedding method. In (Buckley & Qu, 1990) the necessary and sufficient conditions for linear as well as quadratic equations are presented in order to contain a solution in a case that the parameters are either real or complex fuzzy numbers. The homotypic analysis technique is discussed in (Abbasbandy, 2006). The Newton's method is proposed in (Abbasbandy & Ezzati, 2006b). In (Allahviranloo et al., 2007), fixed point technique is suggested in order to solve a system of fuzzy nonlinear equations. Nevertheless, these techniques are so much complex.

DOI: 10.4018/978-1-7998-3479-3.ch022

Iterative technique (Llanas & Sainz, 2006), interpolation technique (Waziri & Majid, 2012) and Runge-Kutta technique (Pederson & Sambandham, 2008) can be applied for obtaining the numerical solution of the fuzzy equation. These techniques can also be applied to fuzzy differential equations (Kajani & Lupulescu, 2009). Neural networks can also be applied in order to find the solutions of the fuzzy equations (Cybenko, 1989; Ito, 2001; Jafari & Razvarz, 2017, 2018, 2015e; Jafari & Yu, 2017b, 2017c; Jafari et al., 2018a, 2018b, 2019b; Jafarian et al., 2016; Jafarian & Jafari, 2012; Yu & Jafari, 2019). In (Buckley & Eslami, 1997), neural network technique is utilized in order to solve the fuzzy quadratic equation. In (Jafari & Razvarz, 2017; Jafarian et al., 2012), the neural network is used in order to obtain the numerical solution of the dual fuzzy equation. In (Mosleh, 2013) neural network method is utilized in order to find the approximate solution of the fully fuzzy matrix equation.

In this book chapter, the neural network technique is utilized in order to estimate the Z-number coefficients of fuzzy equations. The concept of Z-number is used in various areas related to the analysis of the decisions (Kang et al., 2012a; Zadeh, 2006). Z-number is more precise when compared with the fuzzy number. Fewer studies are reported concerned to the topic of Z-numbers (Gardashova, 2014). Converting Z-number into the usual fuzzy set is discussed in (Kang et al, 2012b). In (Aliiev et al., 2015) the theoretical basics of the arithmetic of discrete Z-numbers are presented.

BACKGROUND

This work is the first attempt in finding the Z-number coefficients of fuzzy equations. In order to train the neural network, the backpropagation approach is used. The work is organized as follows. In Section 2, some basic definitions related to the Z-numbers are given. The proposed method for obtaining the Z-number coefficients of the fuzzy equations is demonstrated in Section 3. Some examples with applications in mechanics is given in Section 4. Section 5 concludes the work and provides discussions on further work.

Nonlinear System Modeling With Fuzzy Equations and Z-Numbers

Provide A common discrete-time nonlinear system is depicted as

$$\vartheta_{r+1} = f[\vartheta_r, q_r], \quad w_r = g[\vartheta_r] \quad (1)$$

where $q_r \in \mathbb{R}^n$ is the input vector, $\vartheta_r \in \mathbb{R}^l$ is an internal state vector, also $w_r \in \mathbb{R}^m$ is the output vector. f as well as g are generalized nonlinear smooth functions $f, g \in C^\infty$. Define $W_r = [w_{r+1}^T, w_r^T, \dots]^T$ as well as $Q_r = [q_{r+1}^T, q_r^T, \dots]^T$. Assume $\frac{\partial w}{\partial \vartheta}$ is non-singular at the instance $\vartheta_r = 0$, $Q_r = 0$, so the following model is extracted

$$w_r = Y[w_{r-1}^T, w_{r-2}^T, \dots, q_r^T, q_{r-1}^T, \dots] \quad (2)$$

in which $Y(\bullet)$ is a nonlinear difference equation representing the plant dynamics, q_r as well as w_r are calculable scalar input and output respectively.

The nonlinear systems explained in (2), can be written as the below mentioned linear-in-parameter model

$$w_r = \sum_{i=1}^{\gamma} a_i f_i(\vartheta_r) \quad (3)$$

where a_i is the linear parameter, $f_i(\vartheta_r)$ is nonlinear functions. The variables of this function are quantifying input and output.

The uncertain nonlinear systems can be modeled using the linear-in-parameter models with uncertain parameters. In this book chapter it has been assumed that the model of the nonlinear systems (3) contains uncertainties in the a_i , ϑ_r as well as v_r . These uncertainties have been stated in the form of Z-numbers (Zadeh, 2011).

Definition 1. Suppose c is:

- 1) normal, there is $\varsigma_0 \in \mathfrak{R}$ where $c(\varsigma_0) = 1$,
- 2) convex, $c(\beta\varsigma + (1-\beta)\sigma) \geq \min\{c(\varsigma), c(\sigma)\}$, $\forall \varsigma, \sigma \in \mathfrak{R}, \forall \beta \in [0, 1]$,
- 3) upper semi-continuous on $\mathfrak{R}$, $c(\varsigma) \leq c(\varsigma_0) + \varepsilon$, $\forall \varsigma \in N(\varsigma_0)$, $\forall \varsigma_0 \in \mathfrak{R}$, $\forall \varepsilon > 0$, $N(\varsigma_0)$ is a neighborhood,
- 4) $c^+ = \{\varsigma \in \mathfrak{R}, c(\varsigma) > 0\}$ is compact, so c is a fuzzy variable, $c \in E : \mathfrak{R} \rightarrow [0, 1]$.

The fuzzy variable c is demonstrated as

$$c = (\underline{c}, \overline{c}) \quad (4)$$

in which $\underline{c}$ is the lower-bound variable also, $\overline{c}$ is the upper-bound variable.

Definition 2. The z -number is made up of two components $Z = [c(\varsigma), p]$. The first component $c(\varsigma)$ is the restriction on a real-valued uncertain variable ς . The second component p is a measure of reliability of c . p can be reliability, strength of belief, probability or possibility. The z -number can be stated as Z^+ -number, in a case $c(\varsigma)$ be a fuzzy number also p be the probability distribution of ς . If $c(\varsigma)$ as well as p are fuzzy numbers, the z -number can be stated as Z^- -number.

The Z^+ -number contains more information when compared with the Z^- -number. In this book chapter, the definition of Z^+ -number is utilized, i.e., $Z = [c, p]$, c is a fuzzy number also, p is a probability distribution.

The most common membership functions which define the fuzzy numbers are the triangular function

$$\mu_{\varsigma} = H(s, u, v) = \begin{cases} \frac{\varsigma-s}{u-s} & s \leq \varsigma \leq u \\ \frac{v-\varsigma}{v-u} & u \leq \varsigma \leq v \end{cases} \text{ otherwise } \mu_{\varsigma} = 0 \quad (5)$$

and trapezoidal function

$$\mu_{\varsigma} = H(s, u, v, w) = \begin{cases} \frac{\varsigma-s}{u-s} & s \leq \varsigma \leq u \\ \frac{w-\varsigma}{w-v} & v \leq \varsigma \leq w \text{ otherwise } \mu_{\varsigma} = 0 \\ 1 & u \leq \varsigma \leq v \end{cases} \quad (6)$$

The probability measure can be stated as

$$P = \int_{\mathcal{R}} \mu_c(\varsigma) p(\varsigma) d\varsigma \quad (7)$$

where p is the probability density of ς also, $\mathcal{R}$ is the restriction on p . For discrete z -numbers we have

$$P(c) = \sum_{i=1}^{\gamma} \mu_c(\varsigma_i) p(\varsigma_i) \quad (8)$$

Definition 3. The α -level for fuzzy number c is stated as

$$[c]^\alpha = \{\varsigma \in \mathcal{R} : c(\varsigma) \geq \alpha\} \quad (9)$$

where $0 < \alpha \leq 1$, $c \in E$

Therefore $[c]^0 = c^+ = \{\varsigma \in \mathcal{R}, c(\varsigma) > 0\}$. As $\alpha \in [0, 1]$, $[c]^\alpha$ is bounded, $\underline{c}^\alpha \leq [c]^\alpha \leq \bar{c}^\alpha$. The α -level of c between $\underline{c}^\alpha$ and $\bar{c}^\alpha$ can be defined as

$$[c]^\alpha = (\underline{c}^\alpha, \bar{c}^\alpha) \quad (10)$$

$\underline{c}^\alpha$ as well as $\bar{c}^\alpha$ are the function of α . We define $\underline{c}^\alpha = d_A(\alpha)$, $\bar{c}^\alpha = d_B(\alpha)$, $\alpha \in [0, 1]$.

Definition 4. The α -level of the z -number $Z=(c, p)$ is defined as follows

$$[Z]^\alpha = ([c]^\alpha, [p]^\alpha) \quad (11)$$

where $0 < \alpha \leq 1$. $[p]^\alpha$ is computed by the Nguyen's theorem

$$[p]^\alpha = p([c]^\alpha) = p([\underline{c}^\alpha, \bar{c}^\alpha]) = [\underline{p}^\alpha, \bar{p}^\alpha] \quad (12)$$

where $p([c]^\alpha) = \{p(\varsigma) \mid \varsigma \in [c]^\alpha\}$. Therefore, $[Z]^\alpha$ is stated as

$$[Z]^\alpha = (\underline{Z}^\alpha, \bar{Z}^\alpha) = ((\underline{c}^\alpha, \underline{p}^\alpha), (\bar{c}^\alpha, \bar{p}^\alpha)) \quad (13)$$

where $\underline{p}^\alpha = \underline{c}^\alpha p(\underline{\varsigma}_i^\alpha)$, $\bar{p}^\alpha = \bar{c}^\alpha p(\bar{\varsigma}_i^\alpha)$, $[\varsigma_i]^\alpha = (\underline{\varsigma}_i^\alpha, \bar{\varsigma}_i^\alpha)$.

The same as with the fuzzy numbers (Jafari & Yu, 2015b), three main operations are defined for the z -numbers: $\oplus$, $\ominus$ and $\odot$, which indicate sum, subtract and multiply respectively. In this book chapter, the proposed operations are different from the ones in (Zadeh, 2005).

Suppose $Z_1=(c_1,p_1)$ as well as $Z_2=(c_2,p_2)$ are two discrete z -numbers expressing the uncertain variables ς_1 and ς_2 , so, $\sum_{k=1}^{\gamma}p_1(\varsigma_{1k})=1$, $\sum_{k=1}^{\gamma}p_2(\varsigma_{2k})=1$. The following operation is defined

$$Z_{12} = Z_1 * Z_2 = (c_1 * c_2, p_1 * p_2) \quad (14)$$

where $* \in \{\oplus, \ominus, \odot\}$.

The operations used for the fuzzy numbers are stated as (Jafari, 2015b),

$$[c_1 \oplus c_2]^\alpha = [\underline{c}_1^\alpha + \underline{c}_2^\alpha, \bar{c}_1^\alpha + \bar{c}_2^\alpha]$$

$$[c_1 \ominus c_2]^\alpha = [\underline{c}_1^\alpha - \underline{c}_2^\alpha, \bar{c}_1^\alpha - \bar{c}_2^\alpha] \quad (15)$$

$$[c_1 \odot c_2]^\alpha = \begin{pmatrix} \min \{ \underline{c}_1^\alpha \underline{c}_2^\alpha, \underline{c}_1^\alpha \bar{c}_2^\alpha, \bar{c}_1^\alpha \underline{c}_2^\alpha, \bar{c}_1^\alpha \bar{c}_2^\alpha \} \\ \max \{ \underline{c}_1^\alpha \underline{c}_2^\alpha, \underline{c}_1^\alpha \bar{c}_2^\alpha, \bar{c}_1^\alpha \underline{c}_2^\alpha, \bar{c}_1^\alpha \bar{c}_2^\alpha \} \end{pmatrix}$$

For the discrete probability distributions, the following relation is defined for all $p_1 * p_2$ operations

$$p_1 * p_2 = \sum_i p_1(\varsigma_{1,i}) p_2(\varsigma_{2,(\gamma-i)}) = p_{12}(\varsigma) \quad (16)$$

The Hukuhara difference is defined as (Aliev et al., 2016),

$$Z_1 \ominus_H Z_2 = Z_{12}$$

$$Z_1 = Z_2 \oplus Z_{12} \quad (17)$$

In a case that $Z_1 \ominus_H Z_2$ exists, the α -level can be defined as

$$[Z_1 \ominus_H Z_2]^\alpha = [\underline{Z}_1^\alpha - \underline{Z}_2^\alpha, \bar{Z}_1^\alpha - \bar{Z}_2^\alpha] \quad (18)$$

α Clearly, $Z_1 \ominus_H Z_1 = 0$, $Z_1 \ominus Z_1 \neq 0$.

Moreover, the generalized Hukuhara difference is defined as (Bede & stefanini, 2013),

$$Z_1 \ominus_{gH} Z_2 = Z_{12} \Leftrightarrow \begin{cases} 1) Z_1 = Z_2 \oplus Z_{12} \\ 2) Z_2 = Z_1 \oplus (-1)Z_{12} \end{cases} \quad (19)$$

By taking into consideration the α -level, we have

$$[Z_1 \ominus_H Z_2]^\alpha = [\min\{\underline{Z}_1^\alpha - \underline{Z}_2^\alpha, \bar{Z}_1^\alpha - \bar{Z}_2^\alpha\}, \max\{\underline{Z}_1^\alpha - \underline{Z}_2^\alpha, \bar{Z}_1^\alpha - \bar{Z}_2^\alpha\}]$$

and If also, if $Z_1 \ominus_H Z_2$ exists, $Z_1 \ominus_H Z_2 = Z_1 \ominus_{gH} Z_2$. The conditions for the existence of $Z_{12} = Z_1 \ominus_{gH} Z_2 \in E$ are

$$\begin{aligned} 1) & \begin{cases} \underline{Z}_{12}^\alpha = \underline{Z}_1^\alpha - \underline{Z}_2^\alpha \text{ and } \bar{Z}_{12}^\alpha = \bar{Z}_1^\alpha - \bar{Z}_2^\alpha \\ \text{with } \underline{Z}_{12}^\alpha \text{ increasing, } \bar{Z}_{12}^\alpha \text{ decreasing, } \underline{Z}_{12}^\alpha \leq \bar{Z}_{12}^\alpha \end{cases} \\ 2) & \begin{cases} \underline{Z}_{12}^\alpha = \bar{Z}_1^\alpha - \bar{Z}_2^\alpha \text{ and } \bar{Z}_{12}^\alpha = \underline{Z}_1^\alpha - \underline{Z}_2^\alpha \\ \text{with } \underline{Z}_{12}^\alpha \text{ increasing, } \bar{Z}_{12}^\alpha \text{ decreasing, } \underline{Z}_{12}^\alpha \leq \bar{Z}_{12}^\alpha \end{cases} \end{aligned} \quad (20)$$

where $\forall \alpha \in [0, 1]$.

Suppose c is a triangular function, the absolute value of the z -number $Z=(c,p)$ is defined as

$$|Z(\varsigma)| = (|s_1| + |u_1| + |v_1|, p(|s_2| + |u_2| + |v_2|)) \quad (21)$$

Let c_1 as well as c_2 are triangular functions, the supremum metric for z -numbers $Z_1=(c_1,p_1)$ and $Z_2=(c_2,p_2)$ is expressed as

$$D(Z_1, Z_2) = d(c_1, c_2) + d(p_1, p_2) \quad (22)$$

where $d(\bullet, \bullet)$ is the supremum metrics for fuzzy sets (Jafari, 2015b). $D(Z_1, Z_2)$ has the below mentioned properties,

$$\begin{aligned} D(Z_1 + Z, Z_2 + Z) &= D(Z_1, Z_2) \\ D(Z_2, Z_1) &= D(Z_1, Z_2) \\ D(bZ_1, kZ_2) &= |b| D(Z_1, Z_2) \\ D(Z_1, Z_2) &\leq D(Z_1, Z) + D(Z, Z_2) \end{aligned} \quad (23)$$

where $b \in \mathfrak{R}$, $Z=(c,p)$ is z -number, also c is triangle function.

Definition 5. Suppose $\hat{Z}$ is the space of z -numbers. The α -level of the z -number valued function $H : [0, s] \rightarrow \hat{Z}$ is defined as

$$H(c, \alpha) = [\underline{H}(c, \alpha), \bar{H}(c, \alpha)] \quad (24)$$

where $c \in \hat{Z}$, for each $\alpha \in [0, 1]$.

Using the definition of Generalized Hukuhara difference, the gH -derivative of H at c_0 is defined as

$$\frac{d}{dt} H(c_0) = \lim_{\zeta \rightarrow 0} \frac{1}{\zeta} [H(c_0 + \zeta) \ominus_{gH} H(c_0)] \quad (24)$$

In (25), $H(c_0 + \zeta)$ as well as $H(c_0)$ represent symmetric pattern with Z_1 and Z_2 respectively given in (19).

In this book chapter, the aim of the modeling is to find the Z-number coefficient a_i for the below fuzzy equation

$$w_r^* = \sum_{i=1}^{\gamma} a_i f_i(\vartheta_r) \quad (25)$$

in such a way that the output of the plant w_r approaches to the desired output w_r^* .

Definition 6. The distance between two Z-numbers, $\psi, \phi \in \tilde{Z}$, is described as the Hausdorff metric $D_H[\psi, \phi]$,

$$D_H[\psi, \phi] = \max \left\{ \sup_{(a_1, c_1) \in \psi} \inf_{(a_2, c_2) \in \phi} (d(a_1, a_2) + d(c_1, c_2)), \sup_{(a_1, c_1) \in \phi} \inf_{(a_2, c_2) \in \psi} (d(a_1, a_2) + d(c_1, c_2)) \right\} \quad (27)$$

$d(a, c)$ is the supremum metrics defined for fuzzy sets.

Lemma 1. Let $\varpi \subset \tilde{Z}$ is a compact set, in this case, ϖ is uniformly support-bounded, i.e. there exists a compact set $\Psi \subset \mathfrak{R}$, in such a way that $\forall \psi \in \varpi$,

$$\text{Supp}(\psi) \subset \Psi. \quad (28)$$

Lemma 2. Suppose $\psi, \phi \in \tilde{Z}$, also $\alpha \in (0, 1]$, in this case the following is concluded:

- (i) if $f, g : \mathfrak{R} \rightarrow \mathfrak{R}$ are continuous, $[f(\psi)]^\alpha = f([\psi^\alpha])$ holds;
- (ii) if $f : \mathfrak{R} \rightarrow \mathfrak{R}$ are continuous, so $f(\text{Supp}(\psi)) = \text{Supp}(f(\psi))$.

proof. As (i) concludes from (Yang & Gao, 1993), so just (ii) will be proved. Initially, $\overline{f(D_1)} = f(\overline{D_1})$ is shown for $D_1 \subset \mathfrak{R}$. As $f(D_1) \subset f(\overline{D_1})$, also is closed by the continuity of f , therefore, $\overline{f(D_1)} \subset f(\overline{D_1})$. Also, for randomly given $\theta \in f(\overline{D_1})$, there exists a sequence $\{a_n \mid n \in N\} \subset \mathfrak{R}$, $a \in \mathfrak{R}$, in such a way that $a_n \rightarrow a (n \rightarrow +\infty)$, $\theta = f(a)$. Since f is continues so, $\lim_{n \rightarrow +\infty} f(a_n) = f(a) = \theta$.

However, $f(a_n) \in f(D_1)$, therefore, $\theta \in f(D_1)$. So $\overline{f(D_1)} \subset f(\overline{D_1})$. Hence $\overline{f(D_1)} = f(\overline{D_1})$.

Since,

$$\begin{aligned} \text{Supp}(f(\Psi)) &= \overline{\{\theta \in \mathfrak{R} \mid (f(\Psi))(\theta) > 0\}} \\ f(\text{Supp}(\Psi)) &= f(\overline{\{a \in \mathfrak{R} \mid \Psi(a) > 0\}}) \end{aligned} \quad (29)$$

the following is concluded

$$\begin{aligned} f(\text{Supp}(\Psi)) &= \overline{f(\{a \in \mathfrak{R} \mid \Psi(a) > 0\})} \\ &= \overline{\{f(a) \in \mathfrak{R} \mid \Psi(a) > 0\}} \end{aligned} \quad (30)$$

As, $\{\theta \in \mathfrak{R} \mid (f(\Psi))(\theta) > 0\}$, so

$$\text{Supp}(f(\Psi)) = f(\text{Supp}(\Psi)) \quad (31)$$

Lemma 3. Suppose is a compact set, also as well as are continuous on, in addition

$$|f_1(a) - f_2(a)| < \zeta, \forall a \in G \quad (32)$$

Hence $|\sup_{a \in G_1} f_2(a)| < \zeta$ sup is valid for each compact set $G_1 \subset G$.

proof. As G_1 is a compact set also, f_1 as well as f_2 are continuous on G_1 , so there exist $a_0 \in G_1$, $\hat{a}_0 \in G_1$, in such a way that

$$\begin{aligned} f_1(a_0) &= \sup_{a \in G_1} f_1(a) \\ f_2(\hat{a}_0) &= \sup_{a \in G_1} f_2(a) \end{aligned} \quad (33)$$

Let $|f_1(a_0) - f_2(\hat{a}_0)| \geq \zeta$, so

$$\begin{aligned} f_1(a_0) - f_2(\hat{a}_0) &\leq -\zeta, \\ \text{or } f_1(a_0) - f_2(\hat{a}_0) &\geq \zeta \end{aligned} \quad (34)$$

In the first case of (34), since $f_1(\hat{a}_0) \leq f_1(a_0)$,

$$\begin{aligned} &f_1(\hat{a}_0) - f_2(\hat{a}_0) \\ &\leq f_1(a_0) - f_2(\hat{a}_0) \leq -\zeta \\ &\Rightarrow |f_1(\hat{a}_0) - f_2(\hat{a}_0)| \geq \zeta \end{aligned} \quad (35)$$

holds, that contradicts (32). In the second case (34), as $f_2(a_0) \leq f_2(\hat{a}_0)$, the following is obtained

$$\begin{aligned} &f_1(a_0) - f_2(a_0) \\ &\geq f_1(a_0) - f_2(\hat{a}_0) \geq \zeta \\ &\Rightarrow |f_1(a_0) - f_2(a_0)| \geq \zeta \end{aligned} \quad (36)$$

that contradicts (32). Hence, (34) is not correct, so $-\zeta < f_1(a_0) - f_2(\hat{a}_0) < \zeta$, hence $|f_1(a_0) - f_2(a_0)| < \zeta$, i.e. $|\sup_{a \in G_1} f_1(a) - \sup_{a \in G_1} f_2(a)| < \zeta$. The proof is finalized.

Theorem 1. Suppose $f : \mathfrak{R} \rightarrow \mathfrak{R}$ is a continuous function, so for each compact set $\varpi \subset \hat{Z}_0$ (the set of all the bounded Z-number set) also $\chi > 0$, there exists $a_\iota \in \hat{Z}_0$ $\iota = 1, 2, \dots, \gamma$, in such a manner that

$$d(f(\tilde{\vartheta}), \sum_{\iota=1}^{\gamma} f_{\iota}(\vartheta)a_{\iota}) < \chi \forall \vartheta \in \varpi, \forall \tilde{\vartheta} \in \mathfrak{R} \quad (37)$$

in which χ is a finite number.

proof. The subsequent results will lead to the proof of the Theorem.

Suppose $f : \mathfrak{R} \rightarrow \mathfrak{R}$, f can be extended by the extension principle to the Z-number function that is stated as $f : \hat{Z}_0 \rightarrow \hat{Z}$, also

$$f(\psi_1)(\omega_1) = \vee_{f(\vartheta)=\omega_1} \{\psi_1(\vartheta)\}, \quad \psi_1 \in \hat{Z}_0, \quad \omega_1 \in \mathfrak{R} \quad (38)$$

f is termed as the extended function. Furthermore, $cc(\mathfrak{R})$ is the set of bounded closed intervals of $\mathfrak{R}$. Clearly

$$\psi_1 \in \hat{Z}_0 \Rightarrow \forall \alpha \in (0, 1], [\psi_1]^\alpha \in cc(\mathfrak{R}) \quad (39)$$

Also,

$$\text{Supp}(\psi_1) \in cc(\mathfrak{R}) \quad (40)$$

Hence,

$$\text{Supp}(\psi_1) = [s_1(\psi_1), s_2(\psi_1)] \quad (41)$$

Theorem 2. If $f : \mathfrak{R} \rightarrow \mathfrak{R}$ is a continuous function, so for each compact set $\varpi \subset \hat{Z}_0$, $\tau > 0$ also arbitrary $\varepsilon > 0$, there exists $a_\iota \in \hat{Z}_0$, $\iota = 1, 2, \dots, \gamma$, in such a way that

$$d(f(\vartheta), \sum_{\iota=1}^{\gamma} f_{\iota}(\vartheta)a_{\iota}) < \tau, \quad \forall \vartheta \in \varpi \quad (42)$$

in which, τ is termed as a finite number. The lower as well as the upper limits of the α -level set of Z-number function approach to τ , however the center approaches to ε .

proof. Since $\varpi \subset \hat{Z}_0$ is a compact set, so by implementing Lemma 1, $\Psi \subset \mathfrak{R}$ is the compact set corresponding to ϖ . Furthermore, $\forall \varepsilon > 0$, also using the results of (Cybenko, 1989), there exists $a_\iota \in \mathfrak{R}$, $\iota = 1, 2, \dots, \gamma$, in such a way that

$$|f(\vartheta) - \sum_{i=1}^{\gamma} f_i(\vartheta)a_i| < \varepsilon, \quad \forall \vartheta \in \Psi \quad (43)$$

If $\tilde{f}(\vartheta) = \sum_{i=1}^{\gamma} f_i(\vartheta)a_i$, where $\vartheta \in \mathfrak{R}$, hence

$$|f(\vartheta) - \tilde{f}(\vartheta)| < \varepsilon, \quad \forall \vartheta \in \Psi \quad (44)$$

Theorem 3 will lead to the validation of (42).

Theorem 3. Suppose $\varpi \subset \widehat{Z}_0$ is compact, also Ψ is the corresponding compact set of ϖ and $f, f^E: \mathfrak{R} \rightarrow \mathfrak{R}$ are the continuous functions that,

$$|f(\vartheta) - f^E(\vartheta)| < \zeta, \quad \forall \vartheta \in \Psi \quad (45)$$

where $\zeta > 0$. So, $\forall \psi_1 \in \varpi$, $d(f(\psi_1) - f^E(\psi_1)) \leq \zeta$.

proof. Assume $\psi_1 \in \widehat{Z}$ also $\alpha \in (0, 1]$. Since f as well as f^E are continuous, then $[f(\psi_1)]^\alpha = f([\psi_1]^\alpha)$, and $[f^E(\psi_1)]^\alpha = f^E([\psi_1]^\alpha)$ are valid by Lemma 2. Hence, the following result is obtained using,

$$\begin{aligned} D_H([f(\psi_1)] - [f^E(\psi_1)]) &= D_H(f([\psi_1]^\alpha) - f^E([\psi_1]^\alpha)) \\ &= \sup_{|n|=1} \{ |s(n, f([\psi_1]^\alpha)) - s(n, f^E([\psi_1]^\alpha))| \} \end{aligned} \quad (46)$$

Since $n \in \mathfrak{R} : |n|=1$, the following is valid,

$$\begin{aligned} |s(n, f([\psi_1]^\alpha)) - s(n, f^E([\psi_1]^\alpha))| &= \sup \{ |nj| : j \in f([\psi_1]^\alpha) \} \\ &\quad - \sup \{ |nj| : j \in f^E([\psi_1]^\alpha) \} = \sup \{ |nf(\vartheta)| : \vartheta \in [\psi_1]^\alpha \} \\ &\quad - \sup \{ |nf^E(\vartheta)| : \vartheta \in [\psi_1]^\alpha \} \end{aligned} \quad (47)$$

Also, taking into consideration the conditions in the theorem, the following is obtained

$$|nf(\vartheta) - nf^E(\vartheta)| = |f(\vartheta) - f^E(\vartheta)| < \zeta, \quad \forall \vartheta \in [\psi_1]^\alpha \quad (48)$$

Hence, using (46), (47) as well as Lemma 3, the following relation is extracted which proves the theorem,

$$\begin{aligned} D_H([f(\psi_1)]^\alpha, [f^E(\psi_1)]^\alpha) &< \zeta \Rightarrow d(f(\psi_1), f^E(\psi_1)) \\ &= \sup_{\alpha \in (0, 1]} \{ D_H([f(\psi_1)]^\alpha, [f^E(\psi_1)]^\alpha) \} \leq \zeta \end{aligned} \quad (49)$$

Neural Network Approach for Z-number Parameter Approximation

In this section, a neural network is designed in order to demonstrate the fuzzy equation, see Figure 1. The input of the neural network is the Z-numbers ϑ_r , also the output is the Z-number w_r . The proposed neural network finds a_i in such a way that the output of the neural network w_r approaches to the desired output w_r^* .

Figure 1. Neural network model

The Z-number input ϑ_r is initially implemented to α -level as in (11)

$$[\vartheta_r]^\alpha = (\underline{\vartheta}_r^\alpha, \bar{\vartheta}_r^\alpha) \quad (50)$$

Afterwards, we have the following relation in the hidden unit

$$[\Omega_i]^\alpha = (f_i(\underline{\vartheta}_r)^\alpha, f_i(\bar{\vartheta}_r)^\alpha) \quad i = 1 \dots \gamma \quad (51)$$

The output of the neural network is

$$[w_r]^\alpha = \{ \sum_{i \in A} \Omega_i^\alpha \underline{a}_i^\alpha + \sum_{i \in B} \bar{\Omega}_i^\alpha \underline{a}_i^\alpha, \sum_{i \in A'} \bar{\Omega}_i^\alpha \bar{a}_i^\alpha + \sum_{i \in B'} \Omega_i^\alpha \bar{a}_i^\alpha \} \quad (52)$$

where $A = \{i | \underline{a}_i^\alpha \geq 0\}$, $B = \{i | \underline{a}_i^\alpha < 0\}$, $A' = \{i | \bar{a}_i^\alpha \geq 0\}$, $B' = \{i | \bar{a}_i^\alpha < 0\}$.

For training the weights, a cost function is defined for the Z-numbers. The training error is defined as follows

$$e_r = w_r^* - w_r \quad (53)$$

where $[w_r^*]^\alpha = (\underline{w}_r^{*\alpha}, \bar{w}_r^{*\alpha})$, $[w_r]^\alpha = (\underline{w}_r^\alpha, \bar{w}_r^\alpha)$, $[e_r]^\alpha = (\underline{e}_r^\alpha, \bar{e}_r^\alpha)$. The cost function is defined as

$$\begin{aligned}
\Phi_r &= \underline{\Phi}^\alpha + \overline{\Phi}^\alpha \\
\underline{\Phi}^\alpha &= \frac{1}{2} \left(\underline{w}_r^{*\alpha} - \underline{w}_r^\alpha \right)^2 \\
\overline{\Phi}^\alpha &= \frac{1}{2} \left(\overline{w}_r^{*\alpha} - \overline{w}_r^\alpha \right)^2
\end{aligned} \tag{54}$$

$\Phi_r \rightarrow 0$ signifies that $[w_r]^\alpha \rightarrow [w_r^*]^\alpha$.

The gradient technique is utilized in order to train the Z-number weight $a_i = (\underline{a}_i, \overline{a}_i)$. $\frac{\partial \Phi_r}{\partial a_i}$ is computed as follows

$$\begin{aligned}
\frac{\partial \Phi_r}{\partial a_i} &= \frac{\partial \Phi_r^\alpha}{\partial \underline{w}_r^\alpha} \frac{\partial \underline{w}_r^\alpha}{\partial \underline{a}_i} \frac{\partial \underline{a}_i^\alpha}{\partial a_i} + \frac{\partial \Phi_r^\alpha}{\partial \overline{w}_r^\alpha} \frac{\partial \overline{w}_r^\alpha}{\partial \overline{a}_i} \frac{\partial \overline{a}_i^\alpha}{\partial a_i} \\
&= -(\underline{w}_r^{*\alpha} - \underline{w}_r^\alpha) \left(\sum_{i \in A} \underline{\Omega}_i^\alpha + \sum_{i \in B} \overline{\Omega}_i^\alpha \right) \Gamma_1 \\
&\quad - (\overline{w}_r^{*\alpha} - \overline{w}_r^\alpha) \left(\sum_{i \in A} \overline{\Omega}_i^\alpha + \sum_{i \in B} \underline{\Omega}_i^\alpha \right) \Gamma_2
\end{aligned} \tag{55}$$

where $\Gamma_1 = (1 - \alpha, \underline{p}^\alpha)$ and $\Gamma_2 = (1 - \alpha, \overline{p}^\alpha)$.

The Z-number coefficient a_i is updated as

$$\begin{aligned}
\underline{a}_i(r+1) &= \underline{a}_i(r) - \eta \frac{\partial \Phi_r}{\partial \underline{a}_i} \\
\overline{a}_i(r+1) &= \overline{a}_i(r) - \eta \frac{\partial \Phi_r}{\partial \overline{a}_i}
\end{aligned} \tag{56}$$

where η is the training rate $\eta > 0$. In order to increase the training process, a momentum term is added as

$$\begin{aligned}
\underline{a}_i(r+1) &= \underline{a}_i(r) - \eta \frac{\partial \Phi_r}{\partial \underline{a}_i} + \gamma [\underline{a}_i(r) - \underline{a}_i(r-1)] \\
\overline{a}_i(r+1) &= \overline{a}_i(r) - \eta \frac{\partial \Phi_r}{\partial \overline{a}_i} + \gamma [\overline{a}_i(r) - \overline{a}_i(r-1)]
\end{aligned} \tag{57}$$

where $\gamma > 0$.

Learning Algorithm

- Step 1: Select the training rates $\eta > 0$, $\gamma > 0$, also the stopping criterion $\overline{\Phi} > 0$. The initial Z-number vector $A = (a_1, \dots, a_l)$ is chosen arbitrarily. The initial learning iteration is and the initial learning error is $\Phi = 0$.
- The following steps should be repeated for $\alpha = \alpha_1, \dots, \alpha_m$, till all the training data are implemented
 - Forward computation: Compute the α -level of the Z-number output w_r using the α -level of the Z-number input ϑ_r , and the Z-number connection weight A .
 - Back-propagation: Adjust Z-number parameters a_i , $i = 1, \dots, \gamma$, utilizing the cost function for the α -level of the Z-number output w_r , and the Z-number target output w_r^* .
 - Stopping criterion: Compute the cycle error Φ_r , $\Phi = \Phi + \Phi_r$, $r = r + 1$. In a case that $\Phi > \overline{\Phi}$, let $\Phi = 0$, a new training cycle is begun. Go to (a).

Numerical Example

In this section, some examples with applications are given to show how to apply fuzzy equations to model uncertain nonlinear systems.

Example 1. Three tanks are linked to a pipeline at a constant O , see Figure 2. The water is pumped from one tank to the other two tanks. The system is defined as

$$O = C_1 G_1 \oplus C_2 G_2 \oplus C_3 G_3 \quad (58)$$

where $G_1 = \sqrt{39}$, $G_2 = \frac{1}{2}\sqrt{9}$, $G_3 = 9^2$ are taken to be the quantity of flow, ϑ is taken to be the elapsed time, O is considered to be the high of the pipe, C_1 , C_2 and C_3 are the characteristic coefficients of the pump, which are satisfied in the triangular Z-number uncertainty

$$\begin{aligned} C_1 &= [(3, 5, 8), p(0.81, 0.92, 1)], \\ C_2 &= [(2, 4, 7), p(0.72, 0.85, 0.9)], \\ C_3 &= [(2, 6, 8), p(0.82, 0.86, 0.91)] \end{aligned} \quad (59)$$

Figure 2. Tanks model

Three types of inputs are utilized for training the neural network, where weights are considered as the Z-number parameters of (58). The input data are given as

$$\vartheta = \{[(1, 5, 7), p(0.7, 0.8, 0.9)], [(10, 15, 19), p(0.7, 0.8, 0.91)], [(2, 3, 4), p(0.8, 0.91, 1)] \}$$

The input, ϑ is implemented to (58), and the corresponding outputs data are obtained as

$$O = \left\{ \begin{aligned} &[(628.51, 668.91, 701.21), p(0.7, 0.8, 0.91)], \\ &[(3801.56, 4033.99, 4482.23), p(0.7, 0.82, 0.9)], \\ &[(2481.77, 2893.95, 3301.11), p(0.8, 0.86, 0.9)] \end{aligned} \right\}$$

These input-output pairs have been utilized for training the neural network. The weights are C_1 , C_2 , and C_3 . Table 1 demonstrates the training outcomes. It can be seen that the Z-number coefficients approach to their actual quantity. In this Table, r is taken to be the number of iterations. The approximation errors are shown in Figure 3.

Table 1. Estimation of Z-number coefficients

r		r		r	
1	[(6.27,9.17,11.19),p(0.6,0.8,0.85)]	1	[(5.36,8.28,12.35),p(0.71,0.8,0.92)]	1	[(7.43,10.49,12.37),p(0.7,0.8,0.92)]
2	[(5.91,8.75,10.64),p(0.72,0.8,0.87)]	2	[(4.89,7.77,11.85),p(0.8,0.86,0.94)]	2	[(6.82,9.91,11.87),p(0.6,0.81,0.87)]
	$\vdots$		$\vdots$		$\vdots$
70	[(3.02,5.01,8.03),p(0.81,0.92,1)]	70	[(2.06,4.05,7.03),p(0.72,0.85,0.9)]	70	[(2.04,6.06,8.05),p(0.82,0.86,0.91)]

Figure 3. Approximation errors

In order to change the Z-number into the fuzzy number, the following formula is utilized,

$$v = \frac{\int C \pi_p(C) dC}{\int \pi_p(C) dC} \quad (60)$$

Let $Z = [(6.27, 9.17, 11.19), p(0.6, 0.8, 0.85)]$, so $Z^v = (6.27, 9.17, 11.19; 0.7)$ therefore, $Z' = (\sqrt{0.7} \cdot 6.27, \sqrt{0.7} \cdot 9.17, \sqrt{0.7} \cdot 11.19)$. The results of Table 1 based of fuzzy numbers are demonstrated in Table 2.

Table 2. Estimation of fuzzy number coefficients

r		r		r	
1	(5.24,7.67,9.36)	1	(4.48,6.92,10.33)	1	(6.21,8.77,10.34)
2	(4.94,7.32,8.91)	2	(4.09,6.51,9.91)	2	(5.71,8.29,9.93)
70	(2.69,5.19,6.88)	70	(1.88,4.38,7.71)	70	(2.54,6.17,7.73)

The Z-number $Z=(c,p)=[(6.27,9.17,11.19),p(0.6,0.8,0.85)]$ has an advantage to fuzzy number (5.24,7.67,9.36) . It has more and various information, also the solution generated by Z-number is more precise.

Example 2. The heat source is placed in the left of the insulating materials, see Figure 4. The conductivity coefficient of these materials are $\frac{1}{C_M} = e^9$, $\frac{1}{C_N} = \sqrt{39}$, $\frac{1}{C_Q} = 9$, and 9 is taken to be the elapsed time. The system is defined as (Holman, 1997):

$$S = \frac{M}{C_M} \oplus \frac{N}{C_N} \oplus \frac{Q}{C_Q} \quad (61)$$

The real parameters are

$$\begin{aligned} M &= [(1, 5, 7), p(0.71, 0.8, 0.9)], \\ N &= [(7, 12, 15), p(0.82, 0.92, 1)], \\ Q &= [(2, 4, 8), p(0.81, 0.86, 0.9)] \end{aligned} \quad (62)$$

Three types of inputs are utilized for training the neural network. The input data are given as

Figure 4. Heat source

$$\mathfrak{S} = \{[(2, 4, 9), p(0.8, 0.9, 1)], [(8, 11, 13), p(0.7, 0.81, 0.9)], [(3, 4, 8), p(0.7, 0.8, 0.9)] \}$$

The input, $\mathfrak{S}$ is implemented to (61), and the corresponding outputs data are obtained as

$$S = \left\{ \begin{array}{l} [(430.61, 668.91, 701.21), p(0.7, 0.8, 0.9)], \\ [(1338.22, 1819.12, 2482.23), p(0.7, 0.81, 0.9)], \\ [(765.23, 964.15, 1039.77), p(0.8, 0.86, 0.9)] \end{array} \right\}$$

These input-output pairs have been utilized for training the neural network. The weights are M, N, and Q. The approximation errors are shown in Figure 5. Table 3 demonstrates the training outcomes. It can be seen that the Z-number coefficients approach to their actual quantity. In this Table, r is taken to be the number of iterations.

Figure 5. Approximation errors

The results of Table 3 based of fuzzy numbers are demonstrated in Table 4.

Table 3. Estimation of Z-number coefficients

1	(5.38, 8.32, 11.23), p(0.81, 0.91, 1)]	1	[(10.23, 15.38, 18.41), p(0.7, 0.8, 0.9)]	1	[(6.31, 8.23, 12.42), p(0.7, 0.8, 0.92)]
2	[(4.13, 7.61, 10.49), p(0.7, 0.8, 0.9)]	2	[(9.71, 14.63, 17.65), p(0.8, 0.9, 1)]	2	[(5.61, 7.45, 11.44), p(0.6, 0.81, 0.87)]
	$\vdots$		$\vdots$		$\vdots$
97	[(1.02, 5.01, 7.03), p(0.6, 0.7, 0.8)]	97	[(7.04, 12.07, 15.05), p(0.7, 0.8, 0.9)]	97	[(2.06, 4.05, 8.04), p(0.82, 0.86, 0.91)]

Table 4. Estimation of fuzzy number coefficients

r	M	N	Q
1	(4.04, 6.97, 9.99)	(9.08, 13.98, 17.31)	(4.99, 7.17, 11.06)
2	(3.11, 5.93, 9.51)	(7.99, 13.51, 16.01)	(4.12, 6.12, 10.11)
97	(1.59, 4.12, 6.51)	(6.28, 11.31, 14.75)	(2.55, 3.18, 7.65)

Example 3. The water in the pipe L_1 divides into three pipes L_2 , L_3 and L_4 , see Figure 6. The areas of the pipes are z-numbers,

$$\begin{aligned} D_2 &= [(2, 5, 8), p(0.7, 0.8, 0.9)], \\ D_3 &= [(7, 8, 9), p(0.8, 0.92, 1)], \\ D_4 &= [(3, 6, 9), p(0.8, 0.86, 0.9)] \end{aligned} \quad (63)$$

Figure 6. Water in the pipe model

The water velocities in the pipes are controlled by the valves parameter ϑ , $W_2 = e^{\vartheta}$, $W_3 = \vartheta$ and $W_4 = \sqrt{\vartheta}$. The system is defined as (Streeter, 1999),

$$R = D_2 W_2 \oplus D_3 W_3 \oplus D_4 W_4 \quad (64)$$

The input data are given as

$$\mathcal{G} = \{[(1, 5, 9), p(0.7, 0.8, 0.9)], [(8, 10, 12), p(0.7, 0.81, 0.9)], [(2, 4, 7), p(0.8, 0.9, 1)]\}$$

The corresponding outputs data are obtained as

$$R = \left\{ \begin{array}{l} [(532.74, 741.99, 821.13), p(0.8, 0.9, 1)], \\ [(1465.11, 1902.31, 2552.31), p(0.7, 0.8, 0.9)], \\ [(841.31, 1011.32, 1187.62), p(0.8, 0.85, 0.9)] \end{array} \right\}$$

These input-output pairs have been utilized for training the neural network. The weights are D_2 , D_3 , and D_4 . The approximation errors are shown in Figure 7. Table 5 demonstrates the training outcomes. It can be seen that the Z-number coefficients approach to their actual quantity. In this Table, r is taken to be the number of iterations.

Figure 7. Approximation errors

Table 5. Estimation of Z-number coefficients

r	D_2	r	D_3	r	D_4
1	[(4.45, 8.48, 12.44), p(0.82, 0.92, 1)]	1	[(11.33, 13.42, 15.41), p(0.7, 0.8, 0.9)]	1	[(5.27, 7.39, 10.41), p(0.7, 0.82, 0.92)]
2	[(3.78, 7.68, 11.73), p(0.6, 0.7, 0.85)]	2	[(10.82, 12.91, 14.81), p(0.8, 0.9, 1)]	2	[(4.65, 6.79, 9.81), p(0.6, 0.8, 0.87)]
	$\vdots$		$\vdots$		$\vdots$
169	[(2.02, 5.01, 8.03), p(0.71, 0.8, 0.96)]	169	[(7.05, 8.04, 9.03), p(0.7, 0.8, 0.9)]	169	[(3.05, 6.05, 9.03), p(0.81, 0.86, 0.91)]

Example 4. The deformation of a solid cylindrical rod depends to the stiffness S , forces on it F_1, F_2, F_3 , the positions of the forces A_1, A_2, A_3 and the diameter of the rod $R = \frac{\pi}{4}d^2$. (Tahavvor & Yaghoubi, 2012) see Figure 8. The area of the rod is $R = \frac{\pi}{4}d^2$. The external forces are the function of ϑ , $F_1 = \vartheta$, $F_2 = \sqrt{29}$, $F_3 = 3\vartheta$ (Beer, 1992). The system is defined as (Beer & Johnston, 1992),

$$\frac{-A_1(F_1 + F_2 + F_3)}{R * SS} \oplus \frac{-A_2(F_2 + F_3)}{R * SS} \oplus \frac{-A_3 F_3}{R * SS} = Y \quad (65)$$

where $d=0.02$, $SS=2 \times 10^3$, and,

$$\begin{aligned} \frac{-A_1}{R * SS} &= [(3, 5, 9), p(0.7, 0.81, 0.91)], \\ \frac{-A_2}{R * SS} &= [(6, 8, 10), p(0.8, 0.9, 1)], \\ \frac{-A_3}{R * SS} &= [(3, 7, 11), p(0.8, 0.85, 0.9)] \end{aligned} \quad (66)$$

Figure 8. Solid cylindrical rod

The input data are given as

$$\vartheta = \{[(5, 7, 9), p(0.8, 0.9, 1)], [(9, 11, 13), p(0.7, 0.8, 0.9)], [(1, 4, 9), p(0.7, 0.8, 0.9)]\}$$

The corresponding outputs data are obtained as

$$R = \left\{ \begin{aligned} &[(678.91, 904.34, 1102.11), p(0.8, 0.9, 1)], \\ &[(1994.85, 2201.11, 2487.88), p(0.7, 0.8, 0.9)], \\ &[(452.82, 693.41, 891.12), p(0.8, 0.85, 0.9)] \end{aligned} \right\}$$

These input-output pairs have been utilized for training the neural network. The weights are $\frac{-A_1}{R * SS}$, $\frac{-A_2}{R * SS}$, and $\frac{-A_3}{R * SS}$. For comparing our results, the fuzzy cubic spline technique is utilized (Floreno & Novelli, 1996). Both techniques, the neural network method (the approach suggested in this paper) and the fuzzy cubic spline method are effective in approximating the Z-number coefficients of fuzzy equations. However, the estimated errors related to the neural network technique are minor than the fuzzy cubic spline technique, see Figure 9. Table 6 demonstrates the training outcomes. It can be seen that the Z-number coefficients approach to their actual quantity. In this Table, is taken to be the number of iterations.

Figure 9. Approximation errors of neural network technique and fuzzy cubic spline technique

FUTURE RESEARCH DIRECTIONS

The investigation of the stability of the proposed training algorithm will be the further work.

CONCLUSION

In this book chapter, the neural network approach is utilized in order to estimate the Z-number coefficients of fuzzy equations. The structure of the neural network is based on fuzzy equations. The backpropagation technique is implemented for training the neural network. Simulation results reveal the efficiency of the suggested technique.

KEY TERMS AND DEFINITIONS

Algorithm: An algorithm in mathematics is a procedure, a description of a set of steps that can be used to solve a mathematical computation.

Function: A relation between sets that associates to every element of a first set exactly one element of the second set.

Neural Network: A neural network is a set of layers (a layer has set of neurons) stacked together sequentially.

Nonlinear System: A system in which the change of the output is not proportional to the change of the input.

Polynomial: An expression of more than two algebraic terms, especially the sum of several terms that contain different powers of the same variable(s).

Z-Number: Z-number associated with an uncertain variable X as an ordered pair of fuzzy numbers (A, B) where A represents a value of the variable and B represents an idea of certainty.

Use of Grey Numbers for Evaluating a System's Performance Under Fuzzy Conditions

Michael Voskoglou

Graduate Technological Educational Institute of Western Greece, Greece

INTRODUCTION

In Management a **system** is understood to be a set of interacting components forming an integrated whole and working together for achieving a common target. A factory, a hospital or a bank, constitute standard examples of systems, as well as a physical or biological system, an abstract knowledge system, etc. As a multi- perspective domain systems' theory serves as a bridge for an interdisciplinary dialogue between autonomous areas of study (Balley, 1994, Backlund, 2000). The assessment of a system's performance constitutes a very important part of this theory, because it enables the designers of the system to correct its weaknesses and therefore to increase its effectiveness.

When the performance of a system's components is evaluated by numerical scores, then the traditional way for assessing the system's **mean performance** is the calculation of the average of those scores. However, in order to comfort the reviewer's existing uncertainty about the exact value of the numerical scores corresponding to each of the system's components, frequently in practice the assessment is made not by numerical scores but by linguistic grades, like excellent, very good, good, etc. This involves a degree of fuzziness and makes the calculation of the mean value of those grades impossible.

A popular in such cases method for evaluating the overall system's performance is the calculation of the **Grade Point Average (GPA) index** (e.g. see Voskoglou, 2017b, Chapter 6, p.125). However, GPA is a weighted average in which greater coefficients (weights) are assigned to the higher grades, which means that it reflects not the mean, as we wish, but the **quality performance** of the system.

Analysis of the objectives and of the scope of the present work: In order to overcome the above difficulties, we have utilized in earlier works the system's **total uncertainty** under fuzzy conditions (created by the qualitative assessment of its components) as a measure of its effectiveness (Voskoglou, 2017b, Chapter 5). This manipulation is based on a fundamental principle of the Information Theory according to which the reduction of a system's uncertainty is connected to the increase of information obtained by a system's activity. In other words, lower uncertainty indicates a greater amount of information and therefore a better system's performance with respect to the corresponding activity. However, this method needs laborious calculations, cannot give a precise qualitative characterization of a system's performance and, most importantly, it is applicable for comparing the performance of two different systems with respect to a common activity only under the assumption that the existing uncertainty is the same in the two systems before the activity.

For this reason, **Fuzzy Numbers (FNs)** have been also used in later works for assessing a system's mean performance under fuzzy conditions (Voskoglou, 2017a). However it was observed that, although the calculation of three components is needed for expressing the mean value of the qualitative grades in the form of a **Triangular FN (TFN)**, only the middle component is used for defuzzifying it. The above

DOI: 10.4018/978-1-7998-3479-3.ch023

observation suggests the search for a method analogous to the use of TFNs that possibly reduces the required computational burden. This search led us to utilizing **Grey Numbers (GNs)** (Liu & Lin, 2010) as an alternative tool for assessing a system's mean performance with qualitative grades (Voskoglou & Theodorou, 2017). Although this new method has been proved to be equivalent with the use of TFNs, it needs the calculation of two components only (instead of three) for expressing the mean value of the qualitative grades in the form of a GN.

Synthesis of the present work: Here we are going to present these two innovative methods and to prove their equivalence. The rest of the Chapter is formulated as follows: In the second (background) section the assessment method with the TFNs is sketched and the necessary information about GNs is given, needed for the understanding of the present work. The alternative assessment method using GNs is developed in the third section and its equivalence is proved to the method with TFNs. Examples illustrating those methods are presented in the fourth section and the perspectives of future research on the subject are discussed in the fifth section. Finally, the sixth section includes the conclusions of the present research.

BACKGROUND

Triangular Fuzzy Numbers (TFNs)

The reader is supposed to be familiar with the basic principles of the theory of **Fuzzy Sets (FSs)** and the books of Klir & Folger (1988) and of Dubois & Prade (1980) are proposed as general references on the subject.

A **Fuzzy Number (FN)**, say A , is a **FS** on the set $\mathbf{R}$ of the real numbers, which is **normal** (i.e. there exists x in $\mathbf{R}$ such that $m_A(x) = 1$) and **convex** (i.e. all its **α -cuts** $A^\alpha = \{x \in U: m_A(x) \geq \alpha\}$, α in $[0, 1]$ are closed real intervals) and whose **membership function** $y = m_A(x)$ is a piecewise continuous function. For general facts on FNs the reader may study the classical on the subject book of Kaufmann and Gupta (1994)

A TFN (a, b, c) , with a, b, c real numbers such that $a < b < c$ is the simplest form of a FN representing mathematically the fuzzy statement that “the value of b lies in the interval $[a, c]$ ”. The membership function $y = m(x)$ of (a, b, c) is zero outside the interval $[a, c]$, while its graph in $[a, c]$ consists of two straight line segments forming a triangle with the OX axis (Figure 1).

Figure 1. Graph and Centre of Gravity of the TFN (a, b, c)

Therefore we have:

$$y = m(x) = \begin{cases} \frac{x-a}{b-a}, & x \in [a, b] \\ \frac{c-x}{c-b}, & x \in [b, c] \\ 0, & x < a \text{ or } x > c \end{cases}$$

Using elementary methods of Analytic Geometry it is straightforward to check (Voskoglou, 2017a, Proposition 8) that the coordinates (X, Y) of the *Centre of Gravity (COG)* of the graph of the TFN $A = (a, b, c)$, being the intersection point G of the medians of the corresponding triangle (Figure 1), are calculated by the formulas

$$X(A) = \frac{a+b+c}{3}, Y(A) = \frac{1}{3}(1).$$

The first of formulas (1) can be used to defuzzify the TFN A (*COG defuzzification technique*, e.g. see van Broekhoven, & De Baets, 2006), i.e. to represent it by a crisp number.

The two well known and equivalent to each other methods of defining *arithmetic operations* on FNs (Kaufmann & Gupta, 1991) lead to the following simple rules for the *addition* and *subtraction* of TFNs:

Let $A = (a, b, c)$ and $B = (a_p, b_p, c_p)$ be two TFNs. Then one defines:

- The **sum** $A + B = (a+a_p, b+b_p, c+c_p)$.
- The **difference** $A - B = A + (-B) = (a-c_p, b-b_p, c-a_p)$, where $-B = (-c_p, -b_p, -a_p)$ is defined to be the *opposite* of B .

On the contrary, the **product** and the **quotient** of A and B are FNs, which are not TFNs in general, apart from some special cases.

The following two **scalar operations** can be also defined:

- $k + A = (k+a, k+b, k+c), k \in \mathbf{R}$
- $kA = (ka, kb, kc)$, if $k > 0$ and $kA = (kc, kb, ka)$, if $k < 0$.

The Assessment Method with TFNs

Let $A_i, i = 1, 2, \dots, n$ be TFNs, where n is a non negative integer, $n \geq 2$. Then, the **mean value** of the A_i 's is defined to be the TFN $A = \frac{1}{n}(A_1 + A_2 + \dots + A_n)$.

The qualitative grades $A = \text{excellent}$, $B = \text{very good}$, $C = \text{good}$, $D = \text{fair}$ and $F = \text{unsatisfactory (failed)}$ are considered for the assessment of a system's performance and a scale of numerical scores from 1 – 100 is assigned to them as follows: $A (85 - 100)$, $B (75 - 84)$, $C (60 - 74)$, $D (50 - 59)$ and $F (0 - 49)$ ¹.

Then, each of the above grades can be represented by a TFN, denoted for simplicity by the same letter, in the following way: A = (85, 92.5, 100), B = (75, 79.5, 84), C (60, 67, 74), D (50, 54.5, 59) and F (0, 24.5, 49).

The middle entry of each of the above TFNs is equal to the average of its other two entries. In other words, if

$$A(a_1, b_1, c_1), B(a_2, b_2, c_2), \dots, F(a_5, b_5, c_5), \text{ then } b_i = \frac{a_i + c_i}{2}, i = 1, 2, 3, 4, 5.$$

In order to assess the total system's effectiveness, the performance of each of the system's components is evaluated by one of the above five qualitative grades, which means that one of the TFNs A, B, C, D, F is assigned to each component.

Let n be the total number of the system's components and let n_x denote the number of the components corresponding to the TFN X, where $X = A, B, C, D, F$. Then the mean value M of all those TFNs is equal to the TFN

$$M(a, b, c) = \frac{1}{n} (n_A A + n_B B + n_C C + n_D D + n_F F) \quad (2).$$

Since the calculation of the mean value of the qualitative grades is not possible, it looks logical to consider the TFN M as a fuzzy tool for evaluating the system's mean performance. Then, calculating by the first of formulas (1) the x-coordinate $X(M)$ of the COG of the graph of M, one obtains a crisp quantity for assessing this performance.

Remark: The mean value M is a linear combination of the TFNs A, B, C, D, F of the form $M = k_1 A + k_2 B + k_3 C + k_4 D + k_5 F$, with k_i non negative rational numbers, $i = 1, 2, 3, 4, 5$. Consequently, if $A(a_1, b_1, c_1), B(a_2, b_2, c_2), \dots, F(a_5, b_5, c_5)$ and $M(a, b, c)$, then $M(a, b, c)$

$$M = \sum_{i=1}^5 k_i (a_i, b_i, c_i) = \left(\sum_{i=1}^5 k_i a_i, \sum_{i=1}^5 k_i b_i, \sum_{i=1}^5 k_i c_i \right).$$

Therefore,

$$X(M) = \frac{\sum_{i=1}^5 k_i a_i + \sum_{i=1}^5 k_i b_i + \sum_{i=1}^5 k_i c_i}{3} = \sum_{i=1}^5 k_i \frac{a_i + b_i + c_i}{3} = \sum_{i=1}^5 k_i \frac{a_i + \frac{a_i + c_i}{2} + c_i}{3} = \sum_{i=1}^5 k_i \frac{a_i + c_i}{2} = \sum_{i=1}^5 k_i b_i = b,$$

$$\text{or } X(M) = \frac{a + c}{2} = b \quad (3).$$

Therefore, for the defuzzification of M (a, b, c) one uses only its middle component $b = \sum_{i=1}^5 k_i b_i = b$.

Grey Numbers

Frequently in the everyday life, as well as in many applications of science and engineering, a system's data cannot be easily determined precisely and in practice estimates of them are used. The reason for this is that in large and complex systems, like the socio – economic, the biological ones, etc., many different and constantly changing factors are usually involved, the relationships among which are indeterminate, making their operation mechanisms to be not clear.

Nowadays two are the main tools for handling such approximate data: **Fuzzy Logic (FL)** (see Voskoglou, 2018e) which is based on the notion of *Fuzzy Set (FS)* initiated by Zadeh (1965), and the theory of **Grey System (GS)** initiated by Deng (1982). The GS theory has been mainly developed in China and has currently found important applications in agriculture, economy, management, industry, ecology, environment, meteorology, geography, geology, earthquakes, history, military affairs, sports, traffic, material science, biological protection and in many other fields of the human activity (see Deng, 1989 and its relevant references).

Roughly speaking, a GS is understood to be any investigated system with “poor” information. More explicitly, the systems which lack information, such as structure message, operation mechanism and behaviour document, are referred to as GSs. For example, the human body, agriculture, economy, etc., are GSs. On the grounds of existing grey relations and elements one usually can identify where “grey” means poor, incomplete, uncertain, etc.

The aim of the GS theory is to provide techniques, notions and ideas for analyzing latent and intricate systems, including the establishment of non-function models, the development of a grey process replacing an existing stochastic process, the transformation of disorderly raw data into a more regular series by grey generating techniques instead of modelling with the original data; grey decision making, grey forecasting control replacing classical control, the study of feeling and emotion functions and fields with whitening functions, the study in general of grey mathematics instead of classical mathematics, etc. (for more details see Deng, 1989).

An effective tool for handling the approximate data of a GS is the use of GNs. A GN is an indeterminate number whose probable range is known, but which has unknown position within its boundaries. The GNs are defined with the help of the real intervals. More explicitly, if $\mathbf{R}$ denotes the set of real numbers, a GN, say A , can be expressed mathematically by

$$A[a, b] = \{x \in \mathbf{R} : a \leq x \leq b\}.$$

If $a = b$, then A is called a **white number** and if $A(-\infty, +\infty)$, then it is called a **black number**.

Compared to the interval $[a, b]$, the GN $A[a, b]$ may enrich its uncertainty representation with a **whitening function** $g: [a, b] \rightarrow [0, 1]$ defining the **degree of greyness** $g(x)$, for each x in $[a, b]$. The closer is $g(x)$ to 1, the greater the probability of x to be the representative crisp value of the GN $A[a, b]$. For general facts on GNs we refer to Liu & Lin (2010).

The well known arithmetic of the real intervals (Moore, et al., 1995) has been used to define the basic arithmetic operations among the GNs. More explicitly, if $A[a_1, a_2]$ and $B[b_1, b_2]$ are given GNs and k is a real number, one defines:

- **Addition** by $A + B[a_1 + b_1, a_2 + b_2]$
- **Subtraction** by: $A - B = A + (-B)[a_1 - b_2, a_2 - b_1]$, where $-B[-b_2, -b_1]$ is defined to be the **opposite** of B .

- **Multiplication** by: $A \times B [min\{a_1b_1, a_1b_2, a_2b_1, a_2b_2\}, max\{a_1b_1, a_1b_2, a_2b_1, a_2b_2\}]$
- **Division** by: $A : B = A \times B^{-1} [min\{\frac{a_1}{b_1}, \frac{a_1}{b_2}, \frac{a_2}{b_1}, \frac{a_2}{b_2}\}, max\{\frac{a_1}{b_1}, \frac{a_1}{b_2}, \frac{a_2}{b_1}, \frac{a_2}{b_2}\}]$, where $0 \in [b_1, b_2]$ and $B^{-1} \in [\frac{1}{b_2}, \frac{1}{b_1}]$ is defined to be the **inverse** of B.
- **Scalar multiplication** by: $kA [ka_1, ka_2]$, if k is a positive real number and by $kA [ka_2, ka_1]$, if k is a negative real number.

Observe that $B + (-B) [b_1 - b_2, b_2 - b_1] \neq [0, 0] = 0$, $B + (-B) \neq (-B) + B \neq 0$ and $B \times B^{-1} = B^{-1} \times B \in [\frac{b_1}{b_2}, \frac{b_2}{b_1}] \neq [1, 1] = 1$.

The white number with the highest probability to be the representative real value of the GN $A[a, b]$ is denoted by $w(A)$. The technique of determining the value of $w(A)$ is called **whitenization** of A.

One usually defines $w(A) = (1-t)a + tb$, with t in $[0, 1]$. This is known as the **equal weight whitenization**. When the distribution of A is unknown (i.e. no whitenization function has been defined for A), one takes $t = \frac{1}{2}$, which gives that $w(A) = \frac{a+b}{2}$ (4).

Additional readings for all the topics covered in the present section are provided at the end of the Chapter.

FOCUS OF THE ARTICLE

Methodology

The remark which was stated in the Background Section, following the assessment of a system's mean performance using TFNs, gives the impulse to search for a "formal" assessment procedure, analogous to that with TFNs, that possibly reduces the required computational burden. This led us to utilizing GNs for the system's assessment.

For this, reconsidering the numerical scores A (100-85), B(84-75), C (74-60), D(59-50), F(49-0) attached to the corresponding qualitative grades in the above described method with the TFNs, one corresponds to each grade a GN, denoted for simplicity with the same letter, as follows: $A \in [85, 100]$, $B \in [75, 84]$, $C \in [60, 74]$, $D \in [50, 59]$ and $F \in [0, 49]$.

Then, by assigning to each of the system's components the GN corresponding to its individual performance and by using the same notation and analogous definitions as in the case of the TFNs, one finds that the **mean value** of all those GNs is equal to the GN:

$$M = \frac{1}{n} [n_A A + n_B B + n_C C + n_D D + n_F F] \quad (5)$$

The GN M can be considered as a grey representative of the system's mean performance. But $n_A A \in [85n_A, 100n_A]$, $n_B B \in [75n_B, 84n_B]$, $n_C C \in [60n_C, 74n_C]$, $n_D D \in [50n_D, 59n_D]$ and $n_F F \in [0n_F, 49n_F]$, therefore it turns out that

$M \in [m_1, m_2]$, with

$$m_1 = \frac{85n_A + 75n_B + 60n_C + 50n_D + 0n_F}{n} \text{ and } m_2 = \frac{100n_A + 84n_B + 74n_C + 59n_D + 49n_F}{n}.$$

Since the distributions of the GNs A, B, C, D and F are unknown, the same happens with the distribution of M. Therefore, one finds that

$$w(M) = \frac{m_1 + m_2}{2} \quad (6).$$

The value of $w(M)$ is the crisp outcome to be used for a quantitative estimation of the system's mean performance.

Remarks

1. Taking into account the way of construction of the TFNs and GNs A, B, C, D, F and on comparing the crisp outcomes obtained by the equations (3) and (6) defuzzifying / whitenizing their mean values $M(a, b, c)$ and

$M[m_1, m_2]$ respectively, it turns out that the assessment methods of a system's mean performance using as tools those TFNs and GNs respectively are **equivalent**, since they provide the same assessment outcomes.

2. Also, one observes that in the extreme case where the maximal possible numerical score corresponds to each component for each grade, i.e. the n_A scores corresponding to A are 100, the n_B scores corresponding to B are 84, etc., the mean value of all those scores is equal to b or m_2 respectively. Also, in the opposite extreme case, where the minimal possible numerical score corresponds to each student for each linguistic grade, i.e. the n_A scores corresponding to A are 85, the n_B scores corresponding to B are 75, etc. the mean value of all those scores is equal to a or m_1 respectively. Consequently, the assessment methods with the TFNs and the GNs give a **reliable approximation** of the system's mean performance and therefore they are useful when no numerical scores are used, but the system's performance is assessed by qualitative grades

SOLUTIONS AND RECOMMENDATIONS

In this section three applications to student, athlete and CBR computer systems' assessment are presented as examples for illustrating the use in practice and the equivalence of the two assessment methods with GNs and TFNs respectively and for comparing their outcomes to the classical assessment methods of calculating the mean value of scores and the GPA index. A fourth example follows that requires the solution of a system of equations with grey coefficients for assessing the performance of a football team in two different games

Example 1: The performance of four athletes was assessed by three different experts using a numerical scale from 0 – 100 as follows: A_1 (athlete 1): 48, 51, 52, A_2 : 87, 91, 93, A_3 : 82, 89, 94 and A_4 : 35, 40, 44. It is asked to evaluate the four athletes' mean performance.

Calculation of the mean value of the scores: The mean value of the $4 \times 3 = 12$ scores assigned to the athletes is approximately equal to 67.17, a score demonstrating a good (C) mean performance of the four athletes.

Solution using GNs: It can be observed that 5 of the scores assigned to the athletes correspond to the qualitative grade A, 1 corresponds to B, 2 to D and 4 scores correspond to F. Therefore, by assigning to the above qualitative grades the corresponding GNs one finds that their mean value is

$$M = \frac{1}{12} (5A+B+2D+4F) \in [50, 74.5].$$

Therefore $X(M) = \frac{50 + 74.5}{2} = 62.25$, which demonstrates again to a good (C) mean performance.

Solution using TFNs: In this case one finds the mean value

$$M = \frac{1}{12} (5A+B+2D+4F) = (50, 62.25, 74.5).$$

The defuzzification of M provides the same assessment outcomes with the method using the TFNs.

In concluding, when a system's performance is assessed with numerical scores, the calculation of the mean value of those scores gives the exact outcome for the assessment of its mean performance, whereas the methods using TFNs and GNs give an approximation of it. Therefore the last two methods are useful in practice only when the assessment is made by using qualitative grades.

Example 2: The following Table depicts the performance of two student groups, say G_1 and G_2 , in a common mathematical test involving the solution of three problems on the use of the derivatives for the maximization / minimization of a given function in one variable ².

It is asked to estimate and to compare the mean performance of the two groups in the test.

Table 1. Student performance

Grade	G_1	G_2
A	20	20
B	15	30
C	7	15
D	10	10
F	8	10
Total	60	85

Solution using GNs: Assigning to each student the corresponding GN and calculating the mean values M_1 and M_2 of those GNs for the groups G_1 and G_2 respectively one finds that:

$$M_1 = \frac{1}{60} (20A+15B+7C+10D+8F) \in [62.42, 79.33]$$

$$M_2 = \frac{1}{85} (20A+30B+15C+10D+10F) \in [62.94, 78.94]$$

Therefore the equation (6) gives that $w(M_1) \approx \frac{62.42 + 79.33}{2} \approx 70.88$ and $w(M_2) \approx \frac{62.94 + 78.94}{2} \approx 70.94$.

Consequently both groups demonstrated a good (C) mean performance, with the mean performance of the second group being slightly better.

Solution using TFNs: In this case the calculation of the mean values: gives that

$$M_1 = \frac{1}{60} (20A+15B+7C+10D+8F) = (62.42, 70.88, 79.33)$$

$$M_2 = \frac{1}{85} (20A+30B+15C+10D+10F) = (62.94, 70.94, 78.94)$$

Therefore, using the equation (3) for defuzzifying those mean values one obtains the same assessment outcomes as in the case of GNs. However, the use of TFNs requires the calculation of three components for obtaining the mean values in contrast to the use of GNs, which requires the calculation of two components only.

In concluding, although the above two methods are equivalent, the use of the GNs reduces the required computational burden.

Remark: The GPA index is calculated (Voskoglou, 2017, Chapter 6, p.125) by the formula

$$\text{GPA} = \frac{0n_F + 1n_D + 2n_C + 3n_B + 4n_A}{n} \quad (7).$$

Therefore, one finds that $\text{GPA} = \frac{4.20 + 3.15 + 2.7 + 1.10}{60} \approx 2.48$ for the first and $\text{GPA} = \frac{4.20 + 3.30 + 2.15 + 1.10}{85} \approx 2.47$ for the second group. Thus, in contrast to their mean performance, the first group demonstrated a slightly better quality performance than the second one. The above outcome illustrates the fact that the assessment of a system's quality performance could lead to a different outcome than the assessment of its mean performance.

Example 3 (Assessment of Case-Based Reasoning Systems):

Background: Case-Based Reasoning (CBR) is the process of solving new problems by adapting the solution of similar (analogous) problems solved in the past, which are usually referred as *past cases*. A case - library can be a powerful corporate resource allowing everyone in an organization to tap in it when handling a new problem. A CBR system, usually designed and functioning with the help of computers, allows the case-library to be developed incrementally, while its maintenance is relatively easy and can

be carried out by domain experts. The CBR approach has got a lot of attention over the last 30-40 years, because as an intelligent – systems' method enables information managers to increase efficiency and reduce cost by substantially automating processes.

CBR has been formalized for purposes of computer and human reasoning as a four step process, often referred as the “four R’s”. These steps involve:

- R_1 : **Retrieve** the most similar to the new problem past case.
- R_2 : **Reuse** the information and knowledge of the retrieved case for the solution of the new problem.
- R_3 : **Revise** the proposed solution for solving the new problem.
- R_4 : **Retain** the part of this experience likely to be useful for future problem solving.

The first three of the above steps are not linear, characterized by a backward - forward flow among them. A simplified flow - chart of the CBR process, which is adequate for the purposes of the present paper, is presented in Figure 2:

Figure 2. A simplified flow-chart of the CBR process

More details about the CBR process and a detailed functional diagram illustrating the flow among its four steps are presented in (Voskoglou & Salem, 2014).

The Problem: Consider two CBR systems designed for help desk applications with their libraries containing 105 and 90 past cases respectively. Assume that the two systems' designers have supplied them with the same mechanism (software) that enables the assessment of the degree of success of each one

Table 2. Assessment of the past cases of the two CBR systems – First System

Steps	F	D	C	B	A
R_1	0	0	51	24	30
R_2	18	18	48	21	0
R_3	36	30	39	0	0

Table 3. Assessment of the past cases of the two CBR systems – Second System

Steps	F	D	C	B	A
R_1	0	18	45	27	0
R_2	18	24	48	0	0
R_3	36	27	27	0	0

of their past cases at each step of the CBR process, when used for the solution of new similar problems. Table 2 depicts the degree of success of their past cases in each of the three first steps of the CBR process

Here we shall compare the quality performance of the two systems by calculating the GPA index and their mean performance by applying our assessment methods with the TFNs and the GNs.

- i) **GPA index:** Denote by y_i , $i = 1, 2, 3, 4, 5$ the frequencies of the CBR system's cases whose performance is characterized by F, D, C, B and A respectively, i.e. $y_1 = \frac{n_F}{n}$, $y_2 = \frac{n_D}{n}$, etc. Then the equation (7) gives that

$$\text{GPA} = y_2 + 2y_3 + 3y_4 + 4y_5 \quad (8).$$

In case of the ideal performance ($y_5 = 1$, $y_4 = y_3 = y_2 = y_1 = 0$) we have $\text{GPA} = 4$, while in case of the worst performance ($y_1 = 1$, $y_5 = y_4 = y_3 = y_2 = 0$) we have $\text{GPA} = 0$; therefore $0 \leq \text{GPA} \leq 4$. Consequently, values of GPA greater than 2 could be considered as corresponding to a more than satisfactory system's performance. In our case, the data of Table 4 give the following frequencies:

Table 4. Frequencies of the past cases of the two CBR systems - First System

Steps	y_1	y_2	y_3	y_4	y_5
R_1	0	0	$\frac{51}{105}$	$\frac{24}{105}$	$\frac{30}{105}$
R_2	$\frac{18}{105}$	$\frac{18}{105}$	$\frac{48}{105}$	$\frac{21}{105}$	0
R_3	$\frac{36}{105}$	$\frac{30}{105}$	$\frac{39}{105}$	0	0

Table 5. Frequencies of the past cases of the two CBR systems – Second System

Steps	y_1	y_2	y_3	y_4	y_5
R_1	0	$\frac{18}{90}$	$\frac{45}{90}$	$\frac{27}{90}$	0
R_2	$\frac{18}{90}$	$\frac{24}{90}$	$\frac{48}{90}$	0	0
R_3	$\frac{36}{90}$	$\frac{27}{90}$	$\frac{27}{90}$	0	0

Replacing the values of frequencies from Table 3 in equation (8) one finds the following values for the GPA index:

$$\text{First System: } R_1: \frac{294}{105} = 2.8, R_2: \frac{177}{105} \approx 1.69, R_3: \frac{108}{105} \approx 1.03.$$

$$\text{Second System: } R_1: \frac{189}{90} = 2.1, R_2: \frac{168}{90} \approx 1.87, R_3: \frac{81}{90} = 0.9.$$

The above values of the GPA index show that the first system demonstrated a better quality performance at steps R_1 and R_3 (Retrieve, Revise), whereas the second one demonstrated a better performance at R_2 (Reuse). Further, the two systems' performance was proved to be more than satisfactory in R_1 and less than satisfactory in the other two steps, being worse at R_3 . This was logically expected, since the success in each step depends on the success in the previous steps. Notice that the two systems' performance at the last step R_4 was not examined, since ALL the past cases, even the unsuccessful ones, are retained in a system's library for possible use in future with related new problems; the unsuccessful ones to help for exploring possible reasons of failure to find a solution for the new problem.

Finally, the mean values of the GPA index for the two systems at the three steps R_1 , R_2 and R_3 are approximately equal to 1.84 and 1.62 respectively, showing that the first system demonstrated a better overall quality performance.

- ii) **Use of the TFNs:** From the data of Table 2 one finds that for the first system and in step R_1 we have 51 TFNs equal to $C(60, 67, 74)$, 24 TFNs equal to $B(75, 79.5, 85)$ and 30 TFNs equal to $A(85, 92.5, 100)$. The mean value of all those TFNs, denoted for simplicity by the same letter R_1 , is equal to

$$\begin{aligned} R_1 &= \frac{1}{105} (51C + 24B + 30A) = \frac{1}{105} [(3060, 3417, 3774) + (1800, 1908, 2016) + (2550, 2775, 3000)] \\ &= \frac{1}{105} (7410, 8100, 8790) \approx (70.57, 77.14, 83.71). \end{aligned}$$

Therefore, from equation (3) one gets that $X(R_1) = 77.14$, which shows that the first system demonstrated a very good (B) performance at step R_1 .

In the same way one calculates for the first system the mean values

$$R_2 = \frac{1}{105} (18F + 18D + 48C + 21B) \approx (51, 60.07, 69.14) \text{ and } R_3 = \frac{1}{105} (36F + 30D + 39C) \approx (36.57, 48.86, 61.14),$$

thus obtaining the analogous conclusions for the system's performance at the steps R_2 and R_3 of the CBR process.

Finally, the overall system's performance can be assessed by the mean value

$$R = \frac{1}{3} (R_1 + R_2 + R_3) \approx (52.71, 62.02, 71.33),$$

Therefore, since $X(R) = 62.02$, the system demonstrated a good (C) mean performance.

A similar argument gives for the second system the values $R_1 = (62.5, 68.25, 74)$, $R_2 \approx (45.33, 55.17, 65)$,

$R_3 = (33, .46.25, 59.5)$ and $R \approx (46.94, 56.56, 66.17)$, thus obtaining the analogous conclusions for its mean performance at each step of the CBR process and its overall mean performance.

- iii) **Use of the GNs:** According to this method for the first system and in step R_1 we have 51 GNs equal to $C \in [60, 74]$, 24 GNs equal to $B \in [75, 84]$ and 30 GNs equal to $A \in [85, 100]$. The mean value of all those GNs, denoted by R_1^* , is equal to

$$R_1^* = \frac{1}{105} (51C + 24B + 30A) \in [70.57, 83.71].$$

$$\text{Therefore, } W(R_1^*) = \frac{70.57 + 83.71}{2} = 77.14, \text{ etc.}$$

As we have seen in Section 4 this approach provides in general the same assessment outcomes with the use of TFNs, but, as it becomes more evident from the present example, it reduces significantly the required computational burden.

Table 6 depicts the assessment outcomes obtained in this example

Table 6. Outputs of the Assessment Methods Used in Example 3

METHOD	OUTPUT
GPA index	The first system demonstrated a better overall quality performance and a better quality performance at steps R_1 and R_3 , while the second system performed better at step R_2
TFNs / GNs	The first system demonstrated a better mean performance at all the steps of the CBR process

Example 4: The performance of a football team in two different games is represented by the GNs A and B respectively such that $A + B \in [2, 4]$ and $A \cdot B \in [1, 3]$. It is asked to compare the team's performance in the two games to its top possible performance corresponding to the numerical score 5

Solution: The whitenization of the given sum and product of the GNs A and B leads to the solution of the ordinary system $\begin{cases} x + y = 3 \\ x \cdot y = 2 \end{cases}$, which gives that $x = 2$, $y = 1$ or vice versa. Therefore $w(A) = 2$ and $w(B) = 1$ or vice versa, which means that the team's performance in the two games was equal to the 40% and to the 20% respectively of its top performance.

Remark: The attempt to solve the above problem by applying the definitions of addition and multiplication of GNs presented in the Background section leads to a system of equations with respect to the unknowns a_1, b_1, a_2, b_2 which does not provide a concrete solution. For more details on solving systems of equations with grey data see Voskoglou, 2018a.

FUTURE RESEARCH DIRECTIONS

Although the enormous development of technology during the last years makes easier and more comfortable the human life, it creates in parallel more and more complicated artificial systems, which are difficult to be managed by the traditional scientific methods. As a result, the applications of FL and of the GS theory have been rapidly expanded nowadays covering almost all the sectors of the human activities. In particular the FNs and the GNs have been proved to be efficient tools in handling approximate and uncertain data, playing an important role in fuzzy mathematics and in GS theory respectively, analogous to the role of the regular numbers in crisp mathematics.

Therefore, the attempt to use FNs or / and GNs as tools for solving other practical problems of the everyday life apart from the assessment ones (e.g. see Tanaka & Asai, 1984, Alevizos et al., 2017, etc.) looks as a very interesting and promising direction of future research on the subject. Those problems could be related to topics like Economics, Management, Human Cognition, Computer Science and Information Systems, Sports, Education, Natural Sciences, Psychology, Sociology and many others. It is of worth to notice that such efforts have been already started by the present author for solving equations, systems of equations and linear programming problems with fuzzy or grey data connected to real life applications (Voskoglou, 2018 a, b, c, d).

CONCLUSION

An inevitable consequence of the enormous technological development of the human society during the last years is the continuous development of more and more complicated artificial systems, whose function is characterized by vagueness and/ or uncertainty and it is frequently assessed by using approximate data. As a result the use of methods and principles of FL and of the GS theory have become recently very popular for treating, explaining and improving the performance of such kind of systems. The main tool for the application of the above two approaches is the use of the FNs and of the GNs respectively.

In the present work we have presented two innovative methods using TFNs and GNs for assessing a system's mean performance. Those methods are useful when qualitative grades and not numerical scores are used for the assessment purposes, because in this case the calculation of the mean value of those grades in the traditional way is impossible. Although our two methods were proved to be equivalent, the method with the GNs reduces significantly the required computational burden, since it requires the calculation of two components only (instead of three needed in the case of the TFNs) for obtaining the mean value in the form of a GN. Examples have been also presented on student, athlete, football teams and CBR systems assessment illustrating our methods in practice and showing that the system's quality performance, calculated by the traditional GPA index, may lead to different assessment outcomes. Future research directions on the subject have been also discussed.

KEY TERMS AND DEFINITIONS

Defuzzification: The fuzzy logic's approach for a problem's solution involves the fuzzification of the problem's data by representing them with properly defined fuzzy sets, the evaluation of the fuzzy data in order to express the problem's solution in the form of a unique fuzzy set and the defuzzification of this fuzzy set in order to translate the problem's mathematical solution to the natural language for use with the original real-life problem. The most popular defuzzification method is the Centre of Gravity (COG) Technique in which the corresponding system's fuzzy outputs are represented by the coordinates of the COG of the level's section contained between the graph of the membership function expressing those outputs and the OX axis.

Fuzzy Logic (FL): A logic based on the concept of fuzzy set that, in contrast to the classical bi-valued logic of Aristotle (yes – no), characterizes cases with multiple values.

Fuzzy Number (FN): A fuzzy set A on the set R of the real numbers which is normal (i.e. there exists x in R such that $m_A(x) = 1$) and convex (i.e. all its a -cuts $A^a = \{x \in U: m_A(x) \geq a\}$, a in $[0, 1]$, are closed real intervals) and whose membership function $y = m_A(x)$ is a piecewise continuous function.

Fuzzy Set (FS): A generalization of the concept of crisp set that gives a mathematical formulation to real situations in which certain definitions have not clear boundaries (e.g. the high mountains of a country).. A FS, say A , is characterized by its membership function $y = m_A(x)$ defined on the universal set of the discourse U and taking values in the interval $[0, 1]$, thus assigning to each element x of U a membership degree $m_A(x)$ with respect to A . The closer is $m_A(x)$ to 1, the better x satisfies the characteristic property of A .

Grade Point Average (GPA): A weighted average assigning greater coefficients (weights) to the higher scores and therefore focusing on a system's quality performance.

Grey Number (GN): An indeterminate number whose probable range is known, but which has unknown position within its boundaries. If R denotes the set of real numbers, a GN, say A , can be expressed mathematically with the help of a real interval $[a, b]$ in the form $A[a, b] = \{x \in R : a \leq x \leq b\}$. If $a = b$, then A is called a white number and if $A \in (-\infty, +\infty)$, then it is called a black number. Compared with the interval.

Grey System (GS): A system which lacks information, such as structure message, operation mechanism and behaviour document. Usually, on the grounds of existing grey relations and elements one can identify where “grey” means poor, incomplete, uncertain, etc.

System (in Management): A set of interacting components forming an integrated whole and working together for achieving a common target. A factory, a hospital, or a bank constitute common examples of systems.

Triangular Fuzzy Number (TFN): The simplest form of a FN, whose membership function's graph forms a triangle with the OX-axis. The defuzzification of a TFN $A = (a, b, c)$ may be obtained by considering as its representative crisp value the x-coordinate $X(A) = \frac{a+b+c}{3}$ of the COG of its membership function.

Whitenization of a gn: The process of determining the white number with the highest probability to be the representative real value of a GN $A[a, b]$, which is denoted by $w(A)$. When the distribution of A is unknown, one usually takes $w(A) = \frac{a+b}{2}$.

ENDNOTES

- ¹ One could add more qualitative grades for the assessment, e.g. E = less than satisfactory, could be added between D and F, etc. Also the assignment of the numerical scores to each grade is not uniquely made, depending on the user's personal goals. For example, in a more strict assessment one could take A (90-100), B(80-89), C (70-79), D (60-69), F (0-59), etc. However, the above alternatives do not change the generality of the assessment method proposed.

- ² The following problems were given for solution to the two student groups in the classroom application:

Problem 1: One wants to construct a channel to run water by bending across to its longest side the two edges of a rectangle metallic leaf with dimensions 20 cm and 32 cm respectively, so that to be perpendicular to the other part of the leaf. Assuming that the flow of water is constant, how we can run the maximum possible quantity of the water through the channel?

Problem 2: Among all the cylindrical towers having a total surface of $180\pi \text{ m}^2$, which one has the maximal volume?

Problem 3: A car dealer has a mean annual demand of 250 cars. The annual cost of storing a car is 100 euro and each time he makes a new order he pays an extra amount of 2000 euro for general expenses (transportation, insurance etc). It has been arranged for the cars of the new order to arrive at the time when the last car of the previous order has been sold. How many cars must be ordered each time to minimize the total cost for the dealer?

Cyber Crime, Cyber Bullying, and Digital Terrorism

Cyber Profiling in Criminal Investigation

3

Szde Yu

Wichita State University, USA

INTRODUCTION

As technologies are progressively ingrained in modern life, the line between street crimes and cybercrimes has become gradually blurry. Nowadays, in almost all criminal investigations there is a need for digital investigation to be incorporated as digital information has become relevant and even crucial in most cases. Investigators often have to rely on information retrieved from electronic platforms to find leads and evidence even in crimes that would be traditionally considered street crimes. When comprehensive information is not always attainable, the use of cyber profiling may provide further insight into crucial questions regarding identity, time, and location. Cyber profiling is an analysis on the digital footprints associated with a person whose identity may or may not have been known. When the identity is unknown, the purpose of cyber profiling is primarily about identifying this person or at least creating a workable profile that narrows down suspects. When the identity is already known, the purpose is usually aimed to reveal information that is not readily visible, such as personality, motives, or linkage to other crimes. Besides being subject-centered, cyber profiling can also be event-centered in an attempt to identify time and location. As such, cyber profiling has a wide variety of application in criminal investigation and yet it has not been duly valued. This chapter introduces the fundamentals of cyber profiling and calls for more attention to the development of this technique.

BACKGROUND

To date, there is very little research effort in developing or validating cyber profiling. Therefore, it could be easy to dismiss cyber profiling. Yet, cyber profiling actually has been widely applied in many fields, albeit the name might not be recognized. In other words, many people are already experiencing cyber profiling without knowing it. For instance, some experts tend to make diagnosis about a public figure's personality or state of mind based on comments made on Twitter or other social media. This is basically a form of cyber profiling as the inference is based on digital footprints in the absence of any physical contact. When people do online shopping on certain products and consequently receive promotional advertisements about similar products, it is another example of cyber profiling because the online vendors are profiling shoppers based on their past shopping habits so as to decide what other products they would be interested in as well. Online dating services like Tinder also allows users to do cyber profiling based on only a few photos before they decide which stranger they want to go out on a date with. If cyber profiling can be relied on in the business world and social media, there is no reason why it cannot be utilized in criminal investigations.

DOI: 10.4018/978-1-7998-3479-3.ch024

Currently, criminal investigators are already used to looking for clues in a subject's digital footprints, such as text messages, emails, social media postings, and online shopping or browsing records (Rogers, 2003). However, cyber profiling calls for more attention to the implicit information hidden in the digital footprints. For instance, a man might intentionally avoid expressing his political view on the Internet, but from an analysis on the videos he watched on YouTube and the news websites he frequently visited we can still deduce what this man's political stance is, provided access to such digital footprints is not an issue. The same analysis might shed light on other aspects as well. A study was conducted on Facebook to test the reliability of cyber profiling (Yu, 2013), and it found that using nothing but the participant's Facebook public information, it is possible for a trained profiler to draw largely accurate conclusions about the participant's race, age, gender, and nationality. Moreover, profilers may correctly infer a person's certain personality traits, such as self-control based solely on digital footprints. Lambiotte and Kosinski (2014) also reported the ability to predict personality based on publicly available digital footprints, and they believed such prediction will become more and more accurate as more electronic data are being generated on a daily basis. This type of prediction, aka cyber profiling, can apply to criminal investigation and become a huge help.

Being able to predict personality and characteristics like gender and age has always been an important aspect of criminal profiling (Williams, Nathanson, & Paulhus, 2010; Douglas & Burgess, 1986; Pinizzotto & Finkel, 1990; Canter, 2004). While traditional criminal profiling focuses on behavioral evidence (Turvey, 2011), it becomes crippled when there is no physical trace serving as behavioral evidence. It is a serious issue in modern day investigations where many social interactions only take place in the virtual world (Rogers, 2003). In this regard, cyber profiling uses digital footprints as online behavioral evidence to look for information that can identify characteristics and personality (Yu, 2013). If identifying information can be directly retrieved, then profiling is not needed. For example, it should be easy to tell a person's gender and race by simply looking at the person's selfies. Profiling, however, becomes crucial when such identifying information is vague or deliberately disguised. For instance, when a 46-year-old man pretends to be a 16-year-old girl on the Internet, the photos shared by him probably should not be trusted. In an era where almost everyone has some sort of online presence, it is imperative for criminal investigators to possess the skills and knowledge to verify the authenticity of each online persona they encounter in the course of investigation. This is where cyber profiling begins. Further, from the online persona's digital footprints, investigators should develop skills to find useful clues and evidence that can point to the right person and the right place. Moreover, investigators ought to be able to recognize potential linkage among the digital footprints generated by different online personas in case they are actually owned by the same person. For example, a person can own multiple accounts on Facebook or Twitter and use each account to play a different role in cyberspace. Can the investigators see through this and make connections? This is where cyber profiling helps.

Unfortunately, cyber profiling is not yet a technique that law enforcement agencies are concerned with, even though their agents constantly have to look for clues in a suspect's or a victim's digital footprints. Most of the time, investigators only see what is there to be seen, and tend to overlook what is hidden or implicit in the digital footprints. For example, some researchers found that criminals could easily disguise incriminating communication as email spam and investigators would likely overlook it even when the disguise is very primitive (Yu, 2015). In this regard, cyber profiling may help reveal what is not so obvious to be seen considering incriminating information is usually implicit.

FOCUS OF THE ARTICLE

The Goal of Cyber Profiling

The concept of cyber profiling is derived from criminal profiling. The primary goal of criminal profiling is to provide the criminal investigator with a psychological and social assessment of the subject (Holmes & Holmes, 2009). Cyber profiling shares the same goal, but it relies on the subject's digital footprints instead of physical behavior to perform a psychological and social assessment that helps reveal the subject's identity or criminality. Cyber profiling can be regarded as an extension of criminal profiling, so most principles of criminal profiling still apply in terms of cyber profiling. The following sections discuss the three fundamental elements that constitute cyber profiling, including online behavior analysis, victimology, and cyber-context analysis (Yu, 2013). These three elements are derived from the three elements of behavioral evidence analysis, including forensic analysis, victimology, and crime scene analysis (Turvey, 2011). Behavioral evidence analysis is a profiling approach that focuses on physical behavior, while in the following this focus is adjusted to fit the digital environment where cyber profiling is called for.

Online Behavior Analysis

Any behavior that generates observable digital footprints is considered online behavior (Yu, 2014). For instance, when someone posts a photo on social media, the act of posting the photo is online behavior and the photo is the digital footprint. Even when this photo is deleted, the removal of this photo should be seen as online behavior as well. Accordingly, online behavior analysis focuses on linking digital footprints that are associated with the same person and examine the content of these digital footprints to find identifying information as previously discussed. In addition to the content, online behavior analysis must also examine the rationale behind the online behavior.

For instance, a person's choosing of a password is a form of online behavior, but the reason why this particular password was chosen also matters. If the rationale behind this password choice can be figured out, the password might be correctly disclosed and the rationale can also help reveal some of the subject's thinking patterns and logic. Besides, just because people manifest the same online behavior, it does not necessarily mean their behavior can be explained by the same rationale. For example, some people use Facebook for social-networking, while some might be using it for research only (Yu, 2014).

Moreover, the dynamics of the online behavior is another focal concern in online behavior analysis. Human behavior is not a constant. It may evolve or devolve over time. It may also manifest in response to the environmental restrictions rather than to free will (Yu, 2013; Yu, 2014). Therefore, it is wrong to assume it is not the same person simply because the online behavior changes. Likewise, it is inappropriate to assume it must be the same person simply because the online behavior appears to be the same. Especially on electronic platforms, many things have to be done in a certain way rather than according to personal preferences. For example, some social media sites do not allow users to change the background color, and therefore it is not suitable to use the background color to profile the user's preference. However, to the extent where users can indeed make customized changes, such as profile photos or privacy settings, the changes over time may be worth analyzing because they could be indicative of some personal evolvement, such as mood changes, perception changes, or increased knowledge (Yu, 2014).

To sum up, online behavior analysis should be concerned with three aspects: the content of the behavior, the rationale behind the behavior, and the dynamics of the behavior. Conceivably, the digital footprints attainable may not always be sufficient to support analysis on all three aspects. In such cases, investigators or profilers need to be cautious about any conclusions drawn from cyber profiling. In fact, cyber profiling is aimed to provide directions rather than conclusions. It is an aid, not a solution.

Victimology

In addition to online behavior analysis, similar to criminal profiling, cyber profiling also involves victimology (Turvey, 2011). Victimology is a study of the victim's role in a criminal event as the victim's characteristics and actions/reactions might have directly or indirectly account for the outcome of victimization. Cyber profiling looks into victimology to understand how certain people became victims in an online setting while others in the same settings did not (Yu, 2013). For example, why do some computers become hijacked by ransomware, while others in the same organization do not? Why do some people become a victim of cyber-bullying while others are not being targeted? Questions of this sort are the center of victimology. To be clear, this is not an attempt to blame the victim for victimization. From an investigative perspective, this is a crucial step toward understanding how the victim was chosen, and in turn such understanding may shed more light on how the perpetrator operates and even where they operate (Turvey, 2011).

In criminal investigations, there are three important elements to be determined: motive, means, and opportunity. The motive of a criminal act is not always clear and at times it can be misjudged due to misleading clues. For instance, when a man is killed and his wallet is missing, the motive could be easily assumed to be about money. However, it could be a hate crime at first and the robbery is simply incidental. This is why profiling is needed, because profiling is intended to see beyond what things appear to be. Cyber profiling has the same intention and studying victimology can help reveal all possible motives, not just the ostensible one. Studying the victim also helps reveals the perpetrator's means or capability. Not everyone is capable of committing a crime, especially when it requires advanced computer skills and equipment. Studying victimology can help determine what level of skills and resources this perpetrator may possess. Finally, opportunity is a necessary condition in all crimes. Some criminals have strong motives and great skills, but without opportunity they still cannot make things happen. For instance, a hacker cannot steal money from your bank account if you do not own a bank account. Therefore, cyber profiling studies the victim to see how the victim might have inadvertently provided opportunities for the perpetrator, and more importantly how the perpetrator exploited these opportunities. The way criminals take advantage of opportunities or even the ability to create new opportunities can usually further delineate their means and motives.

In conclusion, cyber profiling studies victims to help verify motive, means, and opportunity. In other words, cyber profiling analyzes more than just the criminal's digital footprints as it analyzes the victim's digital footprints as well. By studying multiple victims, it can detect potential linkage among different incidents even when the criminal does not leave behind too many digital footprints to be profiled.

Cyber-Context Analysis

After analyzing online behavior and victimology, cyber profiling has to also take into account the context in which online behavior takes place. More often than not, human behavior is a reaction to the context, and online behavior is no exception. The same behavior in different contexts might bear very different mean-

ings. Anything taken out of context could be massively misinterpreted. When it comes to cyber-context, it is important to be mindful that online behavior is all computer-mediated. This follows that online behavior is unlikely to be a spontaneous or instinctive response. For example, when a man is enraged, he might slam a door or throw a chair, and that behavior can be seen as a spontaneous response driven by emotion. The behavior probably is not a result of rational thinking. In contrast, for him to go on the Internet to express his anger by sending some angry messages, he must exercise his rational mind to some extent before he can accomplish such online behavior. The fact that all online behavior is computer-mediated makes cyber-context more artificial and contrived. Hence, in cyber profiling it is important to understand the online settings where online behavior and online interaction occur because these settings might be either facilitating or suppressing certain expression of a person's true intent. For instance, typing "LOL" in an online chatroom does not necessarily indicate real laughter. It could be simply seen as an online expression that seems appropriate in a particular cyber-context even when the person does not feel like laughing at all.

In addition to being computer-mediated, many cyber-contexts tend to provide a sense of anonymity. It does not have to be really anonymous. As long as online users feel their true identity is obscure enough, this sense of anonymity tends to result in lowered inhibition that could potentially lead to more deviance (Joinson, 1999; Kabay, 1998; Suler & Phillips, 1998). The connotation is that in such seemingly anonymous contexts, people might be more prone to express their true opinions or to reveal the dark side of their personality (Yu, 2013). As a result, profilers might notice inconsistent patterns between a subject's online behavior and daily behavior. On the other hand, when anonymity is not so assured, most people tend to have a heightened self-awareness (Gonzalez & Hancock, 2011), which could lead to an attempt to hide their true feelings or to manipulate the observer's perception as a way of self-promotion (Gonzalez & Hancock, 2011; Mehdizadeh, 2010; Stefanone et al., 2011; Wilson et al., 2010). Consequently, online behavior in these cyber-contexts is more likely to reveal what people want the audience to see instead of what they really are. Either way, profilers cannot just look at online behavior and assume it is always a truthful reflection of the subject's personality or genuine thought. Hence, the cyber-context must be analyzed as part of cyber profiling to take into account this audience effect.

The Issue

Similar to criminal profiling, cyber profiling requires ample behavioral traces to be reliable. Without abundant digital footprints associated with the subject, profiling might turn into a guessing game based on nothing but the profiler's presumptuous opinions. Therefore, access to relevant digital footprints is vital. Fortunately, nowadays many people, especially the younger generation, seem to be fond of sharing some aspects of their private life on the Internet to the public. When there is a probable cause, it is also not too difficult to obtain a court order for investigators to gain access to less public information, such as online communication and file storage. However, it may not be enough as most people's digital life is mostly private. Simply put, you probably do not want people to know about most of the things you do on your phone or computer, for whatever reasons. Hence, the ability to uncover all hidden digital footprints is a big challenge. Another frequently encountered problem is to correctly associate digital footprints with the right person. Sometimes the investigators have no problem gaining digital footprints from a variety of sources but do not know with whom these footprints should be associated. As a result, the investigators could be using only a fraction of the usable materials due to oversight or they could be mixing digital footprints from different contributors. In this regard, someone with expertise in cyber profiling can be of tremendous assistance. Regrettably, such expertise is not being emphasized as most police agencies tend to see only computer forensics as what they need in a digital investigation.

Cyber profiling is not in competition with computer forensics. In fact, it complements computer forensics. Some even argue cyber profiling should be seen as an integral component of computer forensics (Shaw, 2006; Yu, 2013). Some aspects of cyber profiling actually need to be determined by means of computer forensics, such as IP addresses and systemic logs (Steel, 2014). Moreover, cyber profiling can help identify more digital evidence for forensic analysis, and it can help interpret digital evidence and make inference. While computer forensics is about using generalized rules to analyze digital footprints, cyber profiling is looking into the unique circumstances in each case by examining online behavior, victimology, and cyber-context. Again, they are complementary to each other rather than in competition.

Needless to say, it requires a special skill set to analyze digital footprints adequately. The following section outlines the proficiency needed for a qualified cyber profiler.

SOLUTIONS AND RECOMMENDATIONS

Cyber profilers need to be proficient in a few areas, including computer forensics, criminology, Internet settings and cultures, text analytics, cyber-psychology, and reasoning skills. It could be hard for one person to be proficient in all areas as they require different types of training, so cyber profiling should be performed as teamwork if possible. However, a profiler needs to at least dabble at all areas and build some background knowledge in each one of them. For example, if an expert in computer forensics lacks reasoning skills, he or she probably will draw wrong conclusions from the forensic reports. Likewise, a linguist who is unfamiliar with the Internet cultures will be prone to misinterpret the textual interaction in an online setting. More importantly, cyber profilers should always be mindful of the different languages and ethnic cultures that could be easily integrated or intertwined on the Internet, which is much more discernible in the physical world. For example, a Chinese man might rarely speak English in a face-to-face conversation, but could be used to typing English on the Internet simply because it is faster than typing Chinese characters.

While cyber profiling requires expertise from many disciplines built on different theories, some basic principles apply to all of them. These principles are once again derived and adapted from some principles related to criminal profiling.

1. The principle of uniqueness. Every case is unique as no two individuals will develop in exact same fashion and result in the same behavior (Turvey, 2011). The individual context needs to be analyzed separately in each case before behavior can be interpreted accurately. Experience is invaluable but trying to find every answer from the past experience may not work well with a new problem. Especially in terms of cyber profiling, as technologies rapidly advance, old perspectives may not apply to the new case anymore.
2. The principle of behavioral dynamics. People's behavior could evolve or devolve so they do not remain unchanged over time, even when the motive is the same (Turvey, 2011). People change. Sometimes these changes could actually be more noticeable in online behavior, if the behavioral evidence has been preserved over time. Not only can the online behavior change over time, the cyber-context could be changing as well and thus account for behavioral changes.
3. The principle of motivation. All behaviors have underlying motivation, although sometimes the motivation could be subconscious (Turvey, 2011). Profilers should endeavor to uncover the motivation. Online behavior can be complex and one behavior can serve more than one purpose. For instance, an email spammer could use a fake server to cover traces and to bypass spam filters at the

same time (Yu, 2011; Yu, 2015). Conversely, multiple behaviors could be motivated by the same goal. For example, in cyberspace people could be doing different things with only one purpose in mind: to attract more attention. Furthermore, different people could engage in the same behavior for different reasons. One simple example is that while many people can click on the “like” button on Facebook, it does not mean they all “like” it for the same reason (Yu, 2014). This is why analyzing the rationale behind behavior is crucial in online behavior analysis, as previously mentioned.

4. The principle of motivational dynamics. The motive could change during the act (Turvey, 2011). This is especially true when the behavior involves interaction. For example, what started as friendly bantering online could turn into cyberbullying. Usually when the motivation has changed, the ensuing online behavior will change accordingly. However, such changes may not always be evident, especially when the subject deliberately makes an effort to conceal the motivational change. In this case, to better detect motivational dynamics, online behavior needs to be examined in the context as a sequence of events rather than isolated events.
5. The principle of unintended consequences. Behavior could be an unintended result (Turvey, 2011). In a cyber-context, a behavior could easily result from technical unfamiliarity or mistakes, rather than the true intent. This is why sometimes people send a blank email by accident, or reveal sensitive information online without knowing it. Moreover, even with the best intent, people could still provide misinformation, such as a clerical error. This is why it is important for profilers to analyze online behavior in the context.
6. The principle of humanity. While it is easy to focus on the technological aspects in a digital investigation, crime is still essentially a human problem (Yu, 2013). Criminals are not expected to be forthcoming, and this dishonest tendency can affect their digital footprints as well. Even good people still have reasons to be untruthful from time to time, but at the same time some people are actually more likely to show their true colors in an online environment (Suler & Phillips, 1998; Yu, 2015). To better access the human element in each case, cyber profilers need to have a good understanding on human mind and criminality in addition to computer knowledge. Since there is no border on the Internet, the cultural factors are important in the understanding of human mind (Yu, 2013).
7. The principle of subjectivity. Profiling in any form is inevitably subjective (Yu, 2013). Being subjective is not necessarily a bad thing. Many experts are better at their job precisely because their subjective view is superior to that of the ordinary people. Nevertheless, a good profiler should always entertain the possibility of being wrong and avoid succumbing to common logical fallacies or arrogance. It is also imperative for cyber profilers to remember that their subjective perception may not coincide with the perception of their suspect (Yu, 2015). In other words, what makes sense to them may not make sense to you and vice versa. The suspect’s perception of reality should take precedence over the profiler’s subjective perception because the suspect, not the profiler, is the one responsible for the digital footprints being analyzed.
8. The principle of linkage. When dealing with digital footprints, cyber profilers need to be able to discern the source (Yu, 2013; Yu, 2015). If a computer was shared by more than one person, the digital footprints extracted from this computer may have multiple contributors. Conversely, a person may use more than one device or account, and hence leave behind digital footprints on multiple sources. The ability to correctly link digital footprints to the rightful contributor is of the foremost importance to a cyber profiler. False positives would attribute irrelevant digital footprints to a wrong contributor and render cyber profiling unreliable. False negatives could result in an oversight on critical digital footprints and thus make cyber profiling unreliable as well.

FUTURE RESEARCH DIRECTIONS

Cyber profiling or digital footprints analysis deserves more attention in the field of criminal investigation. It is a technique not only helpful but also necessary, given how often crime involves digital footprints nowadays. Future research has two primary goals. First, how to effectively apply cyber profiling in various types of crime needs to be studied. This involves assessing the nature of the crime, identifying relevant digital footprints, acquiring access to such digital footprints, connecting digital footprints to the correct contributor, and producing reliable evidence. Second, research must look into how to perform adequate analysis in a systematic manner so that it is easier to train profilers. When profiling becomes nothing but the profiler's hunch, it is difficult to teach anyone else how to do it. On the other hand, profiling cannot be done by simply following a list of steps, because profiling must maintain flexibility to adjust to the unique circumstances in every case. Put differently, it is unrealistic to expect every profiler can produce the same results by following the same instructions, and it is equally unrealistic to expect the same instructions will suffice in every case. In this regard, research ought to build on what has been studied about criminal profiling and extend it to cyber profiling by recognizing their similarity as well as discrepancy. In this chapter, the discussion of cyber profiling is largely based on the framework of behavioral evidence analysis (Turvey, 2011), but future research might look into other frameworks that take into account more behavioral features in an online setting.

CONCLUSION

Cyber profiling performs an idiographic analysis on a subject's digital footprints which result from the subject's online behavior. It is not generally aimed to create generalizable rules or statistics, although this aim is not entirely objectionable. The primary focus is generally on the particular subject in question. The subject can be a suspect, a victim, or sometimes just a person of interest. The identity of this subject could be known or unknown. Either way, cyber profiling may offer insight into this subject's background, characteristics, and personality. From this, other information may be further inferred, such as whereabouts, personal history, or anything else that helps solve a crime. Cyber profiling can also be event-centered and used to link separate incidents together when the same person is responsible for them. Since cyber profiling relies on digital footprints, the quality and quantity of digital footprints are equally important. Irrelevant (i.e., false positive) or insufficient (i.e., false negative) digital footprints can both be detrimental to profiling. Therefore, the first step of cyber profiling always involves discerning and accessing applicable sources of online behavior, followed by a thorough online behavior analysis, victimology study, and cyber-context analysis, which may in turn point to more useable digital footprints. In addition to the content of online behavior, the rationale and the dynamics of online behavior are also the focal concerns in cyber profiling. Although they may not always be directly visible, this is actually why profiling is needed. Profiling is about reading between the lines, rather than merely describing what can be seen by everyone. Only with a comprehensive understanding of online behavior, victimology, and cyber-context can the resulting digital footprints be correctly interpreted. Cyber profilers may have expertise in diverse areas, but the basic principles apply to all.

KEY TERMS AND DEFINITIONS

Computer Forensics: Searching and analyzing digital evidence that can be used to prove criminality.

Cyber Context: The online settings and interactions in which online behavior occurs.

Cyber Profiling: An idiographic analysis on a subject's digital footprints so as to reveal information that can help identify or better understand the subject.

Digital Footprints: The information about a person that exists on various electronic platforms as a result of this person's online behavior or online activity on those platforms.

False Negative: Wrongfully deem digital footprints as irrelevant and therefore exclude them from analysis.

False Positive: Wrongfully attribute digital footprints to a person when this person did not contribute to such digital footprints.

Online Behavior: A person's online activity that results in digital footprints.

Victimology: The study of the victim's role in a crime based on the assumption that the victim's characteristics or actions may have indirectly facilitated or directly resulted in victimization.

Boko Haram's Feminization, Minorization, and Cyberization of Terrorism: Offering the Cyberterrorism Diffusion Model as Anti-Bokoharamism Tool

University of Maiduguri, Nigeria

INTRODUCTION

Now, it is no longer any news that Boko haram is dreaded because of its brute acts of terrorism — killing everybody indiscreetly, regardless of faith, gender, age or social status despite the group's claims that it's activities are for Islamic proselytization, a claim that most orthodox Muslims the world over have unanimously condemned. However, over the last four years, whatever killing the group perpetrates is perceived by the public as comparatively less dreadful as a boom of a successfully perpetrated suicide attack. This is because following the weakening over the last couple of years (2016 to 2018) of the terrorists by Nigerian joint military troops, they resorted to using a subtler guerrilla war tactic: laying ambush to Nigerian troops convoys (mostly in remote areas), overrunning and pillaging military camps, bases and even barracks as well as attacking and sometimes laying ambush to motorcades of humanitarian aid personnel zigzagging vulnerable communities in the area. But this subtle war tactic seldom yields large number of casualties as the group would want (given the nature of the targets) compared to suicide bomb attacks which often occur in crowded public places like markets and mosques; hence, people tend to be scared more by suicide attacks, and hence the terrorists' infatuation for girl captives and their preference for suicide bombing as a tool for terrorism (Elden, 2014; GTI, 2017, 2016; UNICEF, 2016a).

So far, the nine-year insurgency has had a devastating effect on the society and people — dozens of thousands have been killed, more than a million others have been forced from their homes and properties worth billions of Dollars have been destroyed (*The Independent*, 2017). Scholars and experts have viewed the attack methodologies adopted by the militants from various perspectives with a view to analysing them and proffering solutions to the protracted insurgency for peace to be restored in the society. Whenever war against terrorism is discussed, the issue of 'sustainable peace' cannot be overlooked. Societies may survive relative peaceful atmosphere but effective social, economic, political and cultural development can only be achieved when there is sustainable peace (Abdulazeez, 2017; Ibrahim & Hassan, 2017).

Currently, the dominant paradigm being employed by the Government in the fight against terrorism has largely been militarized action. Despite the flaws observed in this approach especially human rights abuse by the military, a tremendous success has been achieved within the last couple of years, from 2016 to 2017. The employment of military option to combat insurgency and terrorism may be able to 'enforce' peace, or restore peace through gun nozzle. But an 'enforced' peace (as is being done by Nigerian troops fighting Boko haram) may be difficult to last long (Abdulazeez, 2017). Hence, the need for a multifaceted approach to combat terrorism in Nigeria and worldwide. Historically, over the

DOI: 10.4018/978-1-7998-3479-3.ch025

last decade, terrorists have been striving to have a digital footprint in cyberspace (GTI, 2017; Khayat, 2015), this chapter suggests a research model to address issues surrounding cyber terrorism and conflict.

BACKGROUND

A study carried out in the United States (US) has shown that Boko haram's gendered and youth-centric terrorism ballooned after the group understood what *CNN* (2017) reports, "the potency that gender and youth offer in raising its global profile," after the 14 April 2014 kidnapping of the 276 Chibok school-girls, an incident that prompted the 'Bring Back Our Girls' campaign globally. Boko haram has not only realized that leaning against the screen of gender and youth-centrism by using children (mostly girls) as suicide bombers can raise its global profile but also obviously resolved to make this innovative-tactic a tradition and lead other terror groups around the world in the use of children and women as suicide bombers, a phenomenon that, according to Warner and Matfess (2017 August), has shattered demographic stereotypes as to what a suicide bomber looks like.

Since 2009, when it started its terrorism in north-eastern Nigeria (see Figure 1), Boko haram has notoriously achieved two ironic attributes: (i) being the deadliest terror group in the world (even outstripping ISIL and Al-Shabab) from 2014-2015, and (ii) being the first terror group in human history to pioneer the use of more female suicide bombers than male. Available records have shown that Boko haram, a terrorist group that pledged allegiance to ISIL in March 2015 started using suicide bombers on April 8, 2011, that is, about two years after it began insurgency at Suleja town in the Nigerian state of Niger. The attack claimed nine lives including those of eight National Youth Service Corps (NYSC) members (Warner & Matfess, 2017 August). The group started to use women suicide bombers on a large scale in 2014, two months after the Chibok schoolgirls kidnapping. Since then, no other terrorist group in history has used as many female suicide bombers as Boko haram. This incident, "which proved to be the beginning of a terrible end" (Meservey, 2018, paragraph 3, n.p.) was first broke to the world in October 2015 by a global geopolitical intelligence outfit, Stratfor.

Figure 1. A map showing areas of Boko haram attacks in Nigeria and neighboring Cameroon, Chad and Niger, with concentration of the attacks in the country's northeast (Los Angeles Time, 2014)

Prior to 2014, however, the group used only male suicide attackers. (*Financial*, 2017; *The Independent*, 2017; UNICEF, 2016a; UNICEF, 2016b). Again, on February 19, 2018, the militants abducted 110 schoolgirls at Government Girls Science and Technical College in the Yobe State town of Dapchi. In collaboration with Swiss Government and the International Committee for the Red Cross, the Nigerian Government engaged the militants in series of dialogue and negotiations for the safe release of the poor schoolgirls. On March 21, 2018, 30 days after their abduction 105 of them were returned except for a 15-year-old Leah Sharibu, who till the time of this writing has been retained by the terrorists because she refused to denounce her Christian faith (*Channels Tv*, 2018; *News 24*, 2018).

BOKOHARAMISM

Feminization and Minorization of Terrorism

In recent years, there have been regular reports that children are targeted and exposed to attacks and ruthless violence in their homes, street playgrounds and schools. A recent report indicates that from June 2014 to the end of February 2018, Boko haram deployed 469 female suicide bombers in 240 attacks killing 1,259 people (excluding the bombers) and injuring 2,967 others. Most of those incidents (179, 75%) occurred in Nigeria; 48 incidents (20%) occurred in the neighboring Cameroon's region of Far-North; while Chad and Niger republics had six (2%) and seven (3%) respectively. Additionally, majority (133, 55%) of the attacks in Nigeria occurred in Borno State (Pearson, 2018 May).

Additionally, five months after Pearson's (2018 May) report not less than 15 suicide attacks were carried out by the group about 10 of the incidents perpetrated by female 'human bombs' (see Figure 2),

Figure 2. Picture A shows a young female Boko haram suicide bomber rescued by Nigerian security forces before she detonated the explosives strapped around her waist. Picture B shows a young female Boko haram suicide bomber being stripped off the vest of explosives strapped around her waist by Nigerian troops after an unsuccessful suicide mission which culminated in her killing after she refused to obey orders to cast off the IED (Premium Times Nigeria, 2018)

thus yielding a new total of 486 female suicide bombers. The remaining five incidents were perpetrated by young boys. Scores of people were killed, with the highest figure of fatalities in the most recent incidents coming from the twin suicide attacks carried out by two adolescent boys in a market in the Adamawa town of Mubi on May 1, 2018 killing at least 86 and injuring 58 others. In November of the previous year, another attack had killed 50 persons in the same market (*Aljazeera*, 2018 May).

Despite the incidents have drastically reduced since 2016 due to the Government's commitment in the fight against the militants and drawing from Global Terrorism Index's (GTI) estimation that girl more likely to be deployed as suicide attackers than boys at an approximated ratio of four-to-one (GTI, 2017, 2016), one can confidently say that three in every five suicide bombers would be a child and nine in every 10 suicide bombers would be girls. Obviously, so long as Boko haram militancy lasts, more suicide attacks by young girls might be expected. Another key reason the group prefers female suicide attackers is the ease at which females evade security scrutiny than a man strapped with explosive devices could (Sawicki, 2016, July-August).

Bokoharamism is the planned, deliberate and tactical exploitation by terrorist groups of the social value and vulnerability of women and children for deployment to perpetrate suicide bomb attacks to raise the groups' global notoriety, create an unprecedented degree of fear in society and draw global attention, a strategy pioneered by Nigeria's Islamist group, Boko haram. Four years after the emergence of this method of massacre which began in 2014, it continues till the time of this writing. One critical question that needs to be answered has been: 'is Boko haram's deployment of girls and boys suicide attackers a tactic, strategy or concept?'

Firstly, Bokoharamism is a tactic because it involves disposing the children deployed on suicide missions in order of battle-like organizing operations (Sawicki, 2016, July-August), especially the way they are deployed from their base to the manner they approach their targets when they are about to detonate the IEDs strapped on their bodies. This is particularly evident in the group's earlier suicide attack missions. Secondly, Bokoharamism is a strategy because it involves the group's deliberate use of children and women as suicide bombers as a framework or platform upon which the planning and directing a large percentage of its operations and movements within the war theatre (zone) are pivoted with the aim of sustaining its activities and perpetuating its effect in the society (see Warner & Matfess, 2017 August). This is quite evident in the group's current manoeuvres and operations, especially from 2015 when the group's activities turned out to be deadliest till the time of writing this chapter. Thirdly, the term Bokoharamism is a concept since the term itself was constructed from an idea, a thought, a symbol with theoretical underpinning (Elden, 2014; Zenn, 2015 February).

SOLUTIONS AND RECOMMENDATIONS

Cyberization of Terrorism

The literature has shown that Boko haram's global notoriety has been directly or indirectly promoted by cyber technology (Antwi-Boateng, 2017; Elden, 2014; Zenn, 2015 February; Warner & Matfess, 2017 August). Directly, because the group relies on the media to spread propaganda (aimed at waging a psychological warfare on the society) via You Tube and online news sites such as *Sahara Reporters* and *Aljazeera* (Antwi-Boateng, 2017; Elden, 2014; Zenn, 2015 February). Indirectly, because the group benefits from media coverage and reportage of incidents related to its activities. For example, some media outlets report the incidents as 'breaking news' while others as publish them as 'frontpage

headlines.' Giant Tv networks such as *BBC* and *CNN* even go to the extent of attempting to broadcast the incidents live using amateur video footages from citizen journalists (Semetko & Tworzecki, 2017). In fact, with the profound enhancements in Internet technologies, terrorists are making the hay while the sun shines on cyberspace, a phenomenon that calls for serious actions globally to contain their grip on the budding digital media.

The Cyber Terrorism Diffusion Model

The literature shows that terrorists often act as groups, or networks (Rapoport, 2006). This chapter presents a suggested Cyber Terrorism Diffusion Model (CTDM) which focuses on groups' or networks' use of cyber technology (for details see Ibrahim & Hassan, 2017). Generally, there are no standard set of factors for radicalization, extremism or terrorism (Borum, 2017, 2011). However, an extensive literature review has identified six widely cited conceptual models of radicalization as a series of stages (Beadle, 2017). Drawing mainly from the works of Beadle (2017), Borum (2017, 2011), Moghaddam (2005) and Sageman (2008), this model categorizes cyber terrorism into five dimensions, namely (i) instigating factors, (ii) identity factors, (iii) publicity and exposure factors, (iv) group and cyberspace social network factors, and (v) motivational factors. The constructs and variables of the model were derived from those dimensions.

The model has 14 key predictors of use behavior (UB) (or independent variables, with UB as the main dependent variable, DV), three mediator variables and five moderator (control) variables (see Figure 3 and Table 1). The predictors or independent variables (IVs) of the proposed CTDM are perceived attention (PA), perceived recognition (PRC), perceived respectability (PRS), perceived legitimacy (PL), inherent privacy (IP), inherent user-controllability (IUC), perceived self-aggrandizement (PSA), perceived pervasiveness, inherent globality, inherent autonomy, inherent interactivity, crypto-violence agency, crypto-propaganda agency, and cost value.

Figure 3. The proposed Cyber Terrorism Diffusion Model (CTDM)

Note: The original version of this model is presented in Ibrahim and Hassan (2017, p. 50)

Table 1. Operationalization of the proposed CTDM constructs

S/ No.	Construct/ Variable	Category	Definition	Source
1	PA	IV	The degree to which a group or network of users believe that using a cyber technology can draw wider public attention toward them and render the state attentive to their demands.	Altheide (2009); Beadle (2017); Borum (2017, 2011); Corner and Gill (2015)
2	PRC	"	The degree to which a group or network of users believe that using a cyber technology can render the public and state to be aware, and always be conscious of them.	Beadle (2017); Borum (2017, 2011); Chermask and Freilich (2013)
3	PRS	"	The degree to which a group or network of users believe that using a cyber technology can make them garner wider public and state reverence and regard.	Beadle (2017); Borum (2017, 2011); Corner and Gill (2015)
4	PL	"	The degree to which a group or network of users believe that using a cyber technology to diffuse acts of conflict and terrorism is genuinely justifiable and reasonable.	Altheide (2009); Beadle (2017); Borum (2017, 2011); Chermask and Freilich (2013)
5	ICP	"	The motivation a group or network of cyber technology users derive from the intrinsic or built-in secrecy features of the technology to diffuse acts of conflict and terrorism via the Internet unidentified.	Agre and Rotenberg (1997); Beadle (2017); Barnard-Wills and Ashenden (2012); Byford (1998)
6	IUC	"	The motivation a group or network of cyber technology users derive from the intrinsic or built-in user content-generation, profile customization and general user-friendly applications manipulation features.	Beadle (2017); Borum (2017); Bratich (2011); Carpentier (2011); Chen, Thoms and Fu (2008); Chermask
7	PSA	"	The degree to which a group or network of users believe that using a cyber technology increases their self-worth and dignifies their stature.	Borum (2017, 2011); Chermask and Freilich (2013); Corner and Gill (2015); Gandy (2003)
8	PP	"	The degree to which a group or network of users believe that using a cyber technology to diffuse acts of conflict and terrorism can spread their influence extensively and prevalently.	Beadle (2017); Borum (2017, 2011); Chermask and Freilich (2013); Corner and Gill (2015); Eedle (2002)
9	IG	"	The motivation a group or network users derive from the in-built or 'natural' global ubiquity characteristics of cyber technology.	Baran (2008); Beadle (2017); Borum (2017, 2011); Chen, Thoms and Fu (2008)
10	IA	"	The motivation a group or network of users derive from the vast intrinsic or fundamental freedom and independence of cyber technology from any form of organized control.	Barnard-Wills and Ashenden (2012); Beadle (2017); Borum (2017, 2011); Chermask and Freilich (2013);
11	II	"	The motivation a group or network of users derive from the intrinsic or fundamental characteristics of cyber technology that offers virtually unlimited degree of networked interactivity at both human-to-computer, computer-to-computer and human-to-computer-to-human contexts.	Barnard-Wills and Ashenden (2012); Beadle (2017); Borum (2017, 2011); Corner and Gill (2015)
12	CVA	"	The motivation a group or network of users derive from the virtual world of cyber technology that guarantees tolerance to violence or freedom to incite violence.	Barnard-Wills and Ashenden (2012); Beadle (2017); Chermask and Freilich (2013); Corner and Gill (2015)
13	CPA	"	The motivation a group or network of users derive from the virtual world of cyber technology that guarantees freedom to disseminate propaganda content.	
14	CV	"	The degree to which a group or network of users believe that the use of cyber technology is cost-effective in terms of expenditure and cost-reimbursing in terms of income generation and attracting sponsorship.	Beadle (2017); Biernatzki (2002); Borum (2017, 2011a, b & c); Chermask and Freilich (2013)
15	ERF	MEDV	The religious or secular beliefs and convictions that drive or form parts of the fundamental ideological concepts and legitimizing force of the group or network's movement.	Hobson, Bonk, and Inzlicht (2017); Hoffman (1995); Rapoport (2006, 1983); Sageman (2008); Speckhard (2008)
16	BI	"	The deliberative willingness to use a cyber technology by a group or network to perpetrate violence or terrorism.	Beadle (2017); Borum (2017); Corner and Gill (2015); Maruping et al. (2017)
17	BE	"	A group or network's self-reported subjective probability of its performing a specified behavior, based on its cognitive appraisal of volitional and non-volitional behavioral determinants.	Maruping et al. (2017); Venkatesh, Brown, Maruping, and Bala (2008); Venkatesh, Maruping, and Brown (2006)
18	UB	DV	The actual use, manipulation, running and/ or handling of a cyber technology by a group or network for violence or terrorism.	Beadle (2017); Chermask and Freilich (2013); Corner and Gill (2015); Davis (1989); Venkatesh et al. (2003)

continued on following page

Table 1. Continued

S/ No.	Construct/ Variable	Category	Definition	Source
19	EX	MODV	A group or network of users' prior cyber technology use experience.	Beadle (2017); Chermask and Freilich (2013); Maruping et al. (2017); Venkatesh et al. (2003)
20	TS	''	The belief that a technical help or infrastructure exists to guarantee the use of cyber technology for terrorism and conflict.	Borum (2017); Chermask and Freilich (2013); Corner and Gill (2015); Maruping et al. (2017); Venkatesh et al. (2003)
21	GI	''	The belief that important other groups or networks expect that another group or network should use cyber technology to diffuse acts of violence and terrorism.	Chermask and Freilich (2013); Corner and Gill (2015); Lakhani and Wolf (2005); Maruping et al. (2017); Venkatesh et al. (2003); Webber and Kruglanski (2017)
22	GDR	''	Sex role of members of a group or network of cyber technology users.	Ascol, S., Ayachi, W., Lovell, A., McGill, K., Pagrabs, E., and Yandell R. (2018 April); Speckhard, A. (2008)
23	AG	''	Oldness or youngness of members of a group or network of cyber technology users.	Hecker, T., Fetz, S., Ainamani, H., and Elbert, T. (2015 October); Nandi, C., Elbert, T., Bambonye, M., Weierstall, R., Reichert, M., and Zeller, A. (2017); Speckhard, A. (2008 March)

Note: For details of this table, see Ibrahim and Hassan (2017, p. 50)

pervasiveness (PP), inherent globality (IG), inherent autonomy (IA), inherent interactivity (II), crypto-violence agency (CVA), crypto-propaganda agency (CPA) and cost value (CV). The mediator variables are extremist religious fundamentalism (ERF), behavioral intention (BI) and behavioral expectation (BE) all theorized to mediate the links between the 14 IVs and the DV. BI is theorized to be moderated by five variables, namely experience (EX), technical support (TS), group influence (GI), gender (GR) and age (AG). This is because the core concepts of EX, TS and GI have roots in habit (spontaneous or automatic actions), and all behaviors are governed by intention (Maruping, Bala, Venkatesh & Brown, 2017) and rituals for faith-based actions and practices (Hobson, Bonk, & Inzlicht, 2017) where the power of intention is weak (Borum, 2017, 2011; Maruping et al., 2017; Rapoport, 2006; Wiktorowicz, 2004). BE has been found to be a stronger predictor of use behavior (UB) than BI (Ibrahim & Hassan, 2017; Maruping et al., 2017).

FUTURE RESEARCH DIRECTIONS

Terrorism is evil. However, from all indications, it is here to stay for good. The world must rise against it for peace to reign in all nooks and crannies of human society. Given that conflict is human, and terrorism is borne out of conflict both phenomena may be inexterminable (Elden, 2014). Nonetheless, they can be mitigated. Through the ages, the world has had more than enough share of terror and is still experiencing it. Historically and practically, the dominant paradigm in combatting terrorism and resolving violent conflicts has largely been military force. Yet, like wild fires, violent conflicts and acts of terrorism are continuing here and there across the globe, with no foreseeable end (Abdulazeez, 2017). This paper wants to argue that, comparatively, little of non-military force options have been adopted and successfully applied on a global scale in anti-terrorism campaign. Therefore, a mixed approach involving, e.g., communication for development (e.g., dialogue and alternative dispute resolution means) and research-based solutions with gun power is recommended as one of the efficacious ways of combatting terrorism and conflicts that future research should focus on.

Furthermore, given the spate of developments and innovations in information and communication technologies (ICTs) such as the Internet, website, social media, computer, etc., a great deal of acts of terrorism are progressively planned, coordinated and executed online nowadays. This phenomenon has rendered the terrorists have a digital footprint in cyberspace and society and enabled them to recruit and radicalize new members (Brachman, 2006; King & Taylor, 2001). Hence, this chapter recommends that future research should focus on this new, emerging field of study that expands into the areas of conflicts in cyberspace, including state-of-state cyber warfare, cyber conflict, cyber terrorism and cyber militias.

CONCLUSION

Sadly, as this chapter concludes, Boko haram's activities are continuing with no predictable end to them; at least not soon as signalled by the group's continual suicide bombings and attacks on civilian soft targets, military camps and humanitarian aid workers. Sadly too, the deployment of girls, boys and sometimes, young women in suicide missions continues, a phenomenon that casts a heavy shadow of uncertainty over the future of these poor souls in the Boko haram-infested areas. Even as the fight against the terrorists continues unabatedly, humanitarian aid workers providing livelihoods support to more than a million internally displaced persons (IDPs) and journalists working round the clock covering the conflict could be the terrorists' targets in-the-waiting, especially the former. The world must stand together to reaffirm its commitment to protect all vulnerable groups in the conflict zone. Humanitarian workers and journalists should never be a target much as children and women should not be. In fact, under no circumstance whatsoever should anyone be a target of the militants' killing, maiming and abduction.

It is long overdue Boko haram laid down its arms and accepted the amnesty corridor offered by the Nigerian Government. Redress to grievances and differences should be sought through civil and legal means and all ways of expressing grievances capable of breeding conflict and crisis must be avoided. The UN should continue to play a key role in the global war against terrorism, particularly in West Africa and Nigeria. Meanwhile, UNICEF and other humanitarian aid organizations should continue to work with the Nigerian Government and those of neighboring countries to ensure the safe return of all the abducted schoolgirls, humanitarian aid workers and, indeed, all kidnapped persons. In conclusion, this chapter summons the Government and all critical stakeholders to employ all the scientific and non-scientific methods of exterminating Boko haram terrorism for good through these three critical ways:

- (i) building, operating and sustaining a strong, systematic and professional intelligence network;
- (ii) adopting communication for development strategies, e.g., dialogue and alternative dispute resolution as potent tools of anti-terrorism; and
- (iii) adopting the CTDM approach suggested in this chapter in scientific research on issues surrounding not only Boko haram insurgency but all forms of conflict with a view to stopping violent conflicts and maintaining the peace in the society.

KEY TERMS AND DEFINITIONS

Abduction/Kidnapping: The act of capturing, seizing or forceful carrying off vulnerable individuals by armed non-state actors for political, economic, religious, or social goals.

Boko Haram: A group of Islamist insurgents in the northeast of Nigeria who rose against the Government since 2009 and metamorphosed into a terrorist organization over the years. The group's activity has spilled over into the neighboring countries of Cameroon, Chad and Niger and has been responsible for the death of nearly 30,000 people and displacement of nearly 1.5 million others in Nigeria alone.

Bokoharamism: The planned, deliberate, and tactical exploitation by a terrorist group of the social value and vulnerability of minors, specifically creating an unprecedented degree of fear in society and drawing global attention. This strategy was pioneered by Nigeria's Islamist group, the Boko haram.

Bomb: An improvised explosive device (IED) used as a tool for terrorism.

Cyberization: The use of the Internet, or cyberspace on a sustainable basis by a terrorist group, militias, or other similar groups engaged in conflicts to promote and propagate their causes.

Feminization: The deployment of female (often girls and young women) captives on a sustainable basis by terrorist groups and networks as ‘human bombs’ in suicide missions.

Human Bomb: The use by terrorist groups of (human) captives as bombs (or explosives) on a sustainable basis. Terrorist groups such as Boko haram, ISIL and Al Qaeda have been notorious, particularly Boko haram for the deployment of their captives (mostly young girls and boys) as suicide bomb attackers strapped with IED jackets.

Minorization: The deployment of vulnerable persons (girls, boys, and women) captives by terrorist groups and networks as suicide bombers on a sustainable basis.

Suicide: The act of killing oneself with others using IEDs voluntarily or by coercion for political, economic, religious, or social goals.

Terrorism: The threatened or actual use of illegal force and violence by a group or network of non-state actors (whose main targets are not their actual targets) to gain political, economic, religious, or social goals by fear, coercion, or intimidation.

Cyberbullying: Definition, Behaviors, Correlates, and Adjustment Problems

Michelle F. Wright

Pennsylvania State University, USA & Masaryk University, USA

INTRODUCTION

Many youths have embraced digital technologies, such as mobile phones and the Internet. They often use these technologies daily (Lenhart, 2015). There are many benefits associated with youths' use of digital technologies, such as having the opportunity to communicate with anyone at anytime and in any location, access to information for leisure and school purposes at the click of a button, and easy access to entertainment (e.g., playing online games, watching videos). Despite these benefits, there are opportunities for negative interactions and experiences. These negative interactions and experiences might involve receiving unwanted electronic content via videos, images, and text, identity theft, misuse of personal information, utilizing fake or untrue information for school assignments, and sexual predation. Cyberbullying is another risk associated with youths' digital technology use.

Cyberbullying is often conceptualized as an extension of traditional bullying (Bauman, Underwood, & Card, 2013a; Grigg, 2012). Similar to traditional bullying, cyberbullying involves bullying behaviors that are perpetrated with malicious intent to cause harm to victim or victims through digital technology, such as email, instant messaging, social networking websites, and text messaging through mobile devices. The cyber context allows youths to keep their identity private or to remain anonymous. Because cyberbullies can remain anonymous, they often can harm their victims while also removing any concern for the consequences of their actions (Wright, 2014b). Furthermore, anonymity might lead youths to do or say things online that they would never do or say in the offline world. This is known as the online disinhibition effect (Suler, 2004; Wright, 2014a). Another characteristic of cyberbullying is that cyberbullies are capable of harming their victims in a shorter period of time. In particular, cyberbullies can spread a rumor much quicker in the online world than in the offline world. It might take minutes for a rumor to spread to the whole classroom, while it could take hours for this to occur in the offline world. In addition, cyberbullies can target victims as many times as they want and almost anywhere as well. No longer are victims safe in their own homes, as cyberbullying can follow them into their homes and other places they believe are safe. Cyberbullying can involve the bully and victim only, a bully and multiple victims, one bystander, or multiple bystanders. For example, a cyberbully might post a video making fun of someone and this video might receive thousands of watches, whereas being bullied in the lunchroom might be only visible to youths playing attention to what is happening. Due to these characteristics, cyberbullying is distinctive from traditional face-to-face bullying.

The purpose of this chapter is to review literature on cyberbullying among youths in elementary, middle, and high schools. The literature review draws on studies from different disciplines, including psychology, education, media studies, communication, social work, sociology, and computer science. These studies might also include those with cross-sectional, longitudinal, qualitative, quantitative, mixed

DOI: 10.4018/978-1-7998-3479-3.ch026

methods research designs. Another purpose is for these studies to explain cyberbullying in different countries in an effort to provide a much thorough review of the literature. The chapter is divided into six sections: a) background of cyberbullying, b) characteristics and risk factors associated with cyberbullying, c) negative consequences of cyberbullying, d) solutions and recommendations, e) future research directions, and f) conclusion.

BACKGROUND

Cyberbullying involves the use of digital technologies to hostilely and intentionally harass, embarrass, and intimidate others (Smith et al., 2013). The hostility and intentionality portions of this definition are key to defining cyberbullying, as these behaviors must include a desire to maliciously harm the victim or victims. Similar to traditional forms of face-to-face bullying, cyberbullying can sometimes include repetition and an imbalance of power. Repetition of cyberbullying acts is complex as sharing humiliating videos or text messages can be sent to the victim only, one bystander, or multiple bystanders (Bauman et al., 2013b). The nature of repetition in the cyber context makes it easier for bullies to continue the cycle of cyberbullying behaviors. It is possible for cyberbullies to distribute a humiliating video or text message to one person, and then for this person to share the content additional times with other people. The people can then also share the video or text message.

The use of digital technologies is a component of the cyberbullying definition that separates it from the definition of traditional face-to-face bullying (Curelaru, Iacob, & Abalasei, 2009). There are various digital technologies that can be used to perpetrate cyberbullying behaviors, such as sending unkind text messages and emails, theft of identity information, pretending to be someone else, making anonymous phone calls, sharing secrets about the victim by posting or sending the secret to someone else, spreading nasty rumors using social networking websites, threatening to harm someone, or uploading an embarrassing picture or video of the victim with malicious intent (Bauman et al., 2013a). Some other examples of cyberbullying behaviors are similar to those that occur in the offline world, such as harassment, insults, verbal attacks, teasing, physical threats, social exclusion, and humiliation. Cyberbullying can involve distributing explicit or embarrassing video through different mediums, including social networking sites, text messages, and online gaming sites, creating websites to defame someone else, and making fake social networking profiles using someone else's identity (Rideout et al., 2005).

Some cyberbullying behaviors have no offline equivalent, such as happy slapping and flaming (Rideout et al., 2005). Happy slapping is defined as a group of people who randomly insult another person while filming the incident on a mobile phone, and then these individuals will post the image(s) or video(s) online for others to see. Flaming involves posting provocative or offensive messages in a public forum with the intention of provoking an angry response or argument from members of the forum. Although cyberbullying behaviors can occur through different digital technologies, the most frequently used technologies include gaming consoles, instant messaging tools, and social networking websites (Ybarra et al., 2007).

Rates of Cyberbullying Behaviors

It is important to understand the prevalence rates of youths' involvement in cyberbullying as these rates indicate the likelihood that they will be involved in these behaviors. In one study on cyberbullying, Patchin and Hinduja (2006) found that 29% of youth in their sample reported that they were victimized by cyberbullying and that 47% indicated that they had witnessed cyberbullying as bystanders. Similarly,

Kowalski and Limber (2007) found that 11% of the 3,767 middle schoolers, ages 11 through 14, in their study were cyberbullied, 4% bullied others, and 7% were both cybervictim and cyberbully. In another study, Goebert and colleagues (2011) found that 56.1% of Hawaiian youths in their sample, those in grades 9th through 12th, reported that they were cybervictims. Assessing cyberbullying within the past 30 days among 6th through 12th graders, Hinduja and Patchin (2012) found that 4.9% of the youths in their sample admitted to perpetrating cyberbullying.

Cyberbullying studies have also been conducted in Canada. Cappadocia and colleagues (2013) found that 2.1% of Canadian adolescents in their study admitted that they had perpetrated cyberbullying, 1.9% admitted that they were victims of cyberbullying, and 0.6% were classified as both victims and bullies. In another study published in the same year, Bonanno and Hymel (2013) revealed that 6% of adolescents in their sample were cyberbullies, 5.8% were cybervictims only, and 5% were both cyberbullies and cybervictims.

Rates of cyberbullying involvement have been examined among youths in Africa, Asia, Australia, and Europe. Ultimately, these studies highlight the need to focus on cyberbullying. In one study conducted in Sweden, Laftman and colleagues (2013) found that 5% of their 22,544 sample, ages 15-18, were cybervictims, 4% perpetrated cyberbullying, and 2% were classified as both cybervictims and cyberbullies. With a slightly younger sample of Swedish adolescents, those in the 7th through 9th grade, Beckman et al. (2012) classified 1.9% of their sample as cybervictims, 2.9% as cyberbullies, and 0.6% as both cyberbullies and cybervictims. Rates of cyberbullying involvement were similar to those found among adolescents in Ireland. Corcoran and colleagues (2012) found that 6% of adolescents in their sample reported that they were victims of cyberbullying. Slightly higher rates were found by Brighi and colleagues (2012) among their Italian adolescent sample. In this study, 12.5% were identified as cybervictims. Festl and colleagues (2013) found similar prevalence rates among their sample of German adolescents such that 13% were classified as cyberbullies and 11% as cybervictims. Rates of cyberbullying involvement are slightly higher in Israel than other countries in Europe. In particular, Olenik-Shemesh and colleagues (2010) found that 16.5% of the 242 adolescents in their sample were cybervictims. In Lazuras et al.'s (2013) study, they found that 32.4% of their Israeli adolescent sample reported that they were bystanders of cyberbullying.

Many studies have been conducted on the prevalence rates of cyberbullying among Turkish youths. Estimates of cyberbullying victimization among Turkish youths vary, from 18% to 32% (Eruder-Baker, 2010; Yilmaz, 2011). Cyberbullying perpetration rates ranges from 6% through 9% among Turkish youths in a few studies (e.g., Ayas & Horzum, 2012; Yilmaz, 2011). Rates of cyberbullying perpetration were higher in Aricak et al.'s (2008) study. They found that 36% of Turkish secondary school students in their study admitted to being cyberbullies.

Although some studies of cyberbullying involvement have been conducted in Asian countries, this research has been slower to develop. Huang and Chou (2010) reported that 63.4% of the Taiwanese youths in their sample were cyberbystanders, 34.9% were cybervictims, and 20.4% were cyberbullies. Jang and colleagues (2014) found that 43% of the 3,238 Korean adolescents in their study were either cyberbullies or cybervictims. Rates of cyberbullying involvement are similar in studies conducted with youths in China. In their study, Zhou et al. (2013) found that of the 1,438 youths in their sample that 34.8% were classified as cyberbullies and 56.9% as cybervictims. With a focus exclusively on Facebook cyberbullying, 59.4% of Singaporean adolescents in Kwan and Skoric's (2013) study indicated that they were victimized through Facebook and 56.9% admitted to perpetrating cyberbullying. Little attention has been given to understanding cyberbullying involvement among youths in Africa, India, and South America.

Cross-Cultural Differences in Cyberbullying Involvement

Some attention has been given to comparing the prevalence rates of cyberbullying involvement across different countries. Most of this cross-cultural research has compared countries based on independent self-construal (e.g., view self as separate from the social context) or an interdependent self-construal (e.g., view self within the context of their social environment or society). Typically people from Western countries, like the United States, Canada, and England, are reinforced and primed for behaving in ways aligned with an independent self-construal, whereas people from Eastern countries, like China, Korea, and Japan, are reinforced and primed for behavior consistent with an interdependent self-construal. Differences in these self-construals affect people's social behaviors, particularly their involvement in bullying and cyberbullying. Therefore, independent and interdependent self-construals have been used to explain these behaviors.

In one cross-cultural study on differences in cyberbullying, Barlett et al. (2013) found that youths from the United States engaged in more cyberbullying than youth from Japan. Strohmeier and colleagues (2013) found similar results in their study, with Austrian adolescents reporting more cyberbullying perpetration and victimization than Japanese adolescents. Furthermore, Li (2008) reported that Chinese youths engaged in less cyberbullying perpetration in comparison to Canadian youths, although she found no differences in cyber victimization among these samples. Using a different sample, Li (2006) found support similar results, except that Chinese youths reported that they were victimized online more than Canadian youths. Classifying cyberbullying into reactive (i.e., response to provocation) and proactive (i.e., to obtain some sort of goal), Shapka and Law (2013) found that Canadian youths reported less proactive cyberbullying perpetration when compared to East Asian youths. On the other hand, Canadian youths reported more reactive cyberbullying perpetration than East Asian youths.

In the one of the few studies to focus on cross-cultural differences among Asian countries, Wright et al. (2015) found that Indian adolescents reported more cyberbullying perpetration and victimization when compared to adolescents from China and Japan, with Chinese adolescents reporting more of these behaviors in comparison to Japanese adolescents. Wright and colleagues also found that boys from India were more often involved in cyberbullying than boys from China or Japan.

Variations in prevalence rates are due to differences in samples, sampling techniques, and measures used. Considering the literature on cyberbullying involvement in different countries, it is clear that these behaviors are a global concern, warranting additional investigations.

CHARACTERISTICS OF CYBERBULLYING INVOLVEMENT

The first investigations of cyberbullying focused on prevalence rates. However, the differences found across various samples lead to researchers focusing their attention on the characteristics that are associated with youths' involvement in cyberbullying. One of the first variables examined was age. There are mixed findings regarding age differences in cyberbullying. For example, Williams and Guerra (2007) found that physical forms of cyberbullying, like hacking, peaked in middle school, while rates of physical forms of cyberbullying decreased in high school. Opposite findings from these results were found by Wade and Beran (2011), as they found that 9th graders in their sample had the highest risk of being involved in cyberbullying when compared to adolescents in middle school. Consequently, age was not found to be a reliable predictor of youths' cyberbullying involvement.

Gender has also been examined as a risk factor of cyberbullying. Some researchers have found that boys reported that they were more often the perpetrators of cyberbullying when compared to girls (Boulton et al., 2012; Li, 2007; Ybarra et al., 2007). Other research has found that girls were more often victimized by cyberbullying when compared to boys (Hinduja & Patchin, 2007; Kowalski & Limber, 2007). Yet, some researchers (e.g., Dehue, Bolman, & Vollink, 2008; Pornari & Wood, 2010) reported that girls engaged in more cyberbullying perpetration, and that boys experienced more cyber victimization than girls (e.g., Huang & Chou, 2010; Sjurso, Fandrem, & Roland, 2016). There are also other researchers (e.g., Stoll & Block, 2015; Wright & Li, 2013b) who have found no gender differences in youths' involvement in cyberbullying. Given these mixed findings, some researchers have argued for the need to better understand how gender might impact the mediums used and behaviors perpetrated in cyberbullying incidents. In one study on this topic, Wright (in press) found that boys were more likely to be victimized by cyberbullying through gaming consoles and girls perpetrated relational and verbal forms of cyberbullying. Similar to age, gender is an inconsistent predictor of cyberbullying.

Previous involvement in offline forms of bullying are examined as a risk factor associated with cyberbullying involvement. In this research, relationships are usually found between cyberbullying perpetration and traditional face-to-face bullying perpetration, cyber victimization and traditional face-to-face victimization, and traditional face-to-face victimization and cyberbullying perpetration (Barlett & Gentile, 2012; Mitchell et al., 2007; Wright & Li, 2013a; Wright & Li, 2013b).

Another characteristic examined in association with cyberbullying involvement among youths is digital technology. When youths utilized the internet more often, they are also more likely to report being involved in cyberbullying (Ang, 2016; Aricak et al., 2008). Furthermore, cyber victims self-reported using instant messaging tools, email, blogging sites, and online game more often than nonvictims, another finding suggesting the role of digital technology use in cyberbullying involvement (Smith et al., 2008). The link between digital technology use and cyberbullying involvement might be explained by some youths' greater likelihood to disclose personal information online. Disclosing personal information online, like one's geographical location or school name, increases youths' risk for cyberbullying victimization.

Internalizing difficulties, like depression, anxiety, and loneliness, and externalizing difficulties, such as alcohol and drug use, are also related to youths' involvement in cyberbullying. Researchers propose that internalizing and externalizing difficulties reduce youths' ability to utilize effective coping strategies, making them more vulnerable to cyberbullying (Cappadocia et al., 2013; Mitchell et al., 2007). Alcohol and drug use are both associated with youths' involvement in cyberbullying as the perpetrator and victim (Cappadocia et al., 2013; Wright, in press).

Other variables also influence youths' cyberbullying involvement. Higher normative beliefs (i.e., beliefs about the acceptability of behavior) regarding face-to-face bullying and cyberbullying were related positively to cyberbullying perpetration (e.g., Burton, Florell, & Wygant, 2013; Wright, 2014b). Cyberbullies often hold favorable attitudes toward the perpetration of bullying behaviors, which thereby influences them to believe that these behaviors are acceptable to perpetrate. Holding provictim attitudes (i.e., belief that bullying is unacceptable and that defending victims is valuable) is another variable that impacts cyberbullying involvement. Holding lower levels of provictim attitudes, and having lower peer attachment, less self-control and empathy, and greater moral disengagement were each correlates positively with cyberbullying perpetration (e.g., Sevcikova, Machackova, Wright, Dedkova, & Cerna, 2015; Wright et al., 2015).

Many of the studies on the characteristics that influence youths' cyberbullying involvement do not utilize longitudinal designs. In a longitudinal study, Fanti and colleagues (2012) examined children's and adolescents' exposure to violent media, their callous and unemotional traits, and their cyberbul-

lying involvement one year later. Media violence exposure was positively linked to adolescents' cyber victimization one year later. In another longitudinal study, Wright (2014a) found that perceived stress from parents, peers, and academics/school were related to adolescents' cyberbullying perpetration one year later. The research in this section reveals various risk factors and characteristics that increase youths' vulnerability to cyberbullying perpetration and victimization. Most of the literature focuses on *individual-level* risk factors and characteristics that increase youths' vulnerability to cyberbullying. The next sections focus on the role of parents, schools/teachers, and peers in youths' involvement in cyberbullying. Parents, schools/teachers, and peers represented *contextual-level* risk factors.

Parents

Similar to the offline world, some parents monitor their children's activities in the cyber context. In one study, 50% of youths in one sample reported that their parents did not monitor their online activities, although 80% of parents indicated that they monitored their children's online activities (Mason, 2008). In another study, McQuade, Colt, and Meyer (2009) found that 93% of parents indicated that they set limits on their children's online activities, despite 37% of their children reporting that their parents had given them rules concerning their online activities. Both of these studies might indicate that parents overreport how much monitoring they engage in, that parents do not share their monitoring strategies with their children, or that their strategies for monitoring their children's online activities is ineffective because their children do not believe any strategies have been implemented. Parents' role in protecting their children from online risks is important. More research attention should be given to how parents navigate conversations with their children about online risks and opportunities.

Wright (2015) found that parents have a significant role in protecting their children from cyber victimization. Parents who engaged in more mediation of their children's digital technology use reduced the risk of cyberbullying victimization and depression. She concluded that parental mediation buffers against the negative consequences associated with cyberbullying. It could be possible that parents who monitor their children's digital technology use might have more opportunities to discuss the risks associated with technology use. These discussions might increase youths' awareness of the risks associated with cyberbullying and convey to them that negative online behaviors are not acceptable and are punishable. Such a proposal is consistent with research revealing that youths who believe that their parents will punish them for engaging in cyberbullying and other negative behaviors were less likely to engage in cyberbullying (Hinduja & Patchin, 2013; Wright, 2013a). Some research has found that parental monitoring did not influence youths' exposure to online risks. Aoyama and colleagues (2011) found that parental mediation had no impact on youths' involvement in cyberbullying. Their explanation was that many parents lack technological skills and this makes it difficult for them to be sure of how and when to intervene. Such a proposal is consistent with previous research findings in which parents reported that they were not sure how to discuss online activities with their children (Rosen, 2007). This uncertainty might lead some parents to not know to talk to their children about appropriate online behaviors. However, this research is dated and many parents are enjoying the benefits of technology and using digital devices.

Parents who do not enforce or follow-up on the strategies they implement to make the Internet safer for their children might be increasing their children's exposure to online risks. Their children could develop the perception that their parents are unconcerned with their online activities, subsequently increasing their risk of perpetrating cyberbullying. Not only is it important for parents to enforce and implement strategies concerning their children's digital technology use but it is also important for parents to update these strategies as children become older and desire more privacy and independence.

Some research has focused on the family characteristics that could potentially increase youths' risk of cyberbullying involvement. Family income, parental education, and marital status of parents/caregivers was unrelated to youths' cyberbullying involvement (Ybarra & Mitchell, 2004). In later research, Arslan and colleagues (2012) found that parental unemployment was related to youths' cyberbullying perpetration and victimization. Neglectful parenting increased youths' risk of cyberbullying involvement when compared to uninvolved youths (Dehue, Bolman, Vollink, & Pouwelse, 2012). Furthermore, authoritarian parenting style increased youths' experience of cyberbullying as cybervictims.

The literature discussed in this section indicates that parents have an important function in their children's digital lives. The next sections examine literature on the role of schools/teachers and peers in youths' cyberbullying involvement.

Schools

There is much debate concerning schools' role in monitoring and enforcing sanctions for youths' cyberbullying. One of the reasons for this debate is because many cyberbullying incidents occur off school grounds, often making it difficult for schools to know when these situations occur and how to deal with such situations (deLara, 2012; Mason, 2008). Regardless of where cyberbullying incidents occur, many of these incidents involve youths who attend the same school, which could further complicate the schools' role in handling cyberbullying. This is because youths who know each other and who also engage in cyberbullying might increase the likelihood that cyberbullying or knowledge of a cyberbullying situation could spill over into the school environment. This spillover effect could disrupt the learning process and make victims even more fearful.

Despite the potential for cyberbullying to spill over onto school grounds, teachers and administrators can often have very different perceptions of cyberbullying as some of these individuals might perceive cyberbullying as more problematic than others (Kochenderfer-Ladd & Pelletier, 2008). Many times administrators and teachers do not perceive cyberbullying or other types of covert bullying behavior, such as relational bullying, as serious and harmful behaviors (Sahin, 2010). Given these differences, it is not surprising that some teachers tend to encourage prevention programs designed to reduce physical forms of face-to-face bullying more often than other forms of bullying (Tangen & Campbell, 2010). These teachers do not usually understand that there are also harmful consequences associated with bullying and cyberbullying.

There is teacher training that can help teachers recognize cyberbullying and how to deal with it, though this training is often insufficient and does not properly inform teachers of what to do when one of their students is cyberbullied. Teachers can also be unfamiliar with newer technologies, another barrier to them dealing effectively with cyberbullying (Cassidy et al., 2012a). They might not know how to respond to the incident or what strategies to use to alleviate the situation. Even when teachers are concerned about cyberbullying, there are few policies and programs in place at the school level, making it harder for them to implement solutions to help victims (Cassidy, Brown, & Jackson, 2012b).

There are some schools that recognize the importance of implementing effective policies and professional development designed to help teachers, staff, and administrators deal effectively with cyberbullying as these behaviors can have the potential to impact learning (Shariff & Hoff, 2007). When youths are involved in cyberbullying, as perpetrators or victims, they are less likely to perceive their school and teachers positively when compared to uninvolved youths (Bayar & Ucanok, 2012).

Victims of cyberbullying often fear that their classmates might be cyberbullies, which could further disrupt their ability to concentrate on learning in the classroom (Eden, Heiman, & Olenik-Shemesh,

2013). Such disruptions might reduce their academic attainment and performance. Furthermore, lower school commitment and perceptions of a negative school climate increase youths' perpetration of cyberbullying as they feel less connected to their school (Williams & Guerra, 2007).

More training is needed to increase administrators', staffs', and teachers' awareness of cyberbullying. They should work together to develop effective policies at the school level to reduce cyberbullying and implement strategies to handle such incidents. This professional development can increase teachers' self-efficacy for dealing with cyberbullying. When teachers' confidence in their teaching ability increases, they have stronger commitment to their school and desire to learn more about cyberbullying (Eden et al., 2013). Learning more about cyberbullying can increase teachers' awareness of these behaviors and how to deal with cyberbullying, which can reduce youths' involvement in cyberbullying. Teachers who feel more confident in their abilities are more likely to intervene in cyberbullying (Elledge et al., 2013). Intervening in cyberbullying protects adolescents from experiencing these behaviors. Elementary school teachers reported the most motivation for learning about cyberbullying when compared to middle school and high school teachers. This is problematic as cyberbullying involvement increases from elementary school to middle school (Ybarra et al., 2007). Therefore, there is a need for educator training programs aimed at raising awareness of cyberbullying, particularly in the middle school years.

Peers

Peer relationships are important for youths as they help them learn about social norms that govern acceptable and unacceptable behaviors within the peer group. As a consequence of this learning, youths will engage in more of these acceptable behaviors, as dictated by their peers, even if these behaviors are negative. Cyberbullying often involves pre-existing relationships among youths. Therefore, it is not surprising that the best predictor of cyberbullying is the classroom climate in which these behaviors are encouraged (Festl et al., 2013). Believing that one's friends engaged in cyberbullying is a positive predictor of youths' perpetration of cyberbullying (Hinduja & Patchin, 2013). The peer contagion effect might explain these associations. According to this effect, the negative behaviors engaged in by one's friends have the potential to "spread" other youths within their social network (Sijtsema, Ashwin, Simona, & Gina, 2014).

Peer attachment (i.e., belief that peers will be or will not be there for them when they need it) has a relationship to youths' involvement in bullying. Burton et al. (2013) found that lower of peer attachment were associated positively with cyberbullying perpetration and victimization. Other research has revealed that peer rejection increases youths' cyberbullying involvement (Sevcikova et al., 2015; Wright & Li, 2013b). To explain the relationship between peer rejection and cyberbullying involvement, Wright and Li (2012) explained that peer rejection has the potential to trigger negative emotional responses that increase cyberbullying perpetration and victimization. Some research has explored the potential for cyberbullying to promote youths' social standing in their peer group, both online and offline. Given that digital technologies have a prominent role in youths' lives, these technologies can also be used to promote or maintain youths' social standing in the peer group. To investigate this proposal, Wright (2014c) found that perceived popularity (i.e., a reputational type of popularity in the peer group) was related positively to cyberbullying perpetration six months later among adolescents. The literature in this section suggests that it is important to consider the role of peers in youths' cyberbullying involvement.

NEGATIVE CONSEQUENCES OF CYBERBULLYING

The concern with cyberbullying is triggered by its association with various negative social, psychological, behavioral, and academic difficulties that result from youths' exposure to these behaviors. Cyberbullying can disrupt youths' emotional experiences. In the literature, cybervictims report lower levels of global happiness, general school happiness, school satisfaction, family satisfaction, and self-satisfaction (Toledano, Werch, & Wiens, 2015). Cybervictims also indicate that they feel more anger, sadness, and fear when compared to uninvolved youths (Dehue et al., 2008; Machackova, Dedkova, Sevcikova, & Cerna, 2013; Patchin & Hinduja, 2006).

Cyberbullying also negatively effects youths' academic performance. Cyberbullies and cybervictims experience greater academic problems, such as lower motivation for school, poor academic performance, lower academic attainment, and greater school absences (Belae & Hall, 2007; Yousef & Bellamy, 2015). Furthermore, disruptive classroom behaviors, lower grades, and lower test scores are positively associated with youths' cyberbullying perpetration and victimization (Wright, in press).

Cyberbullies and cybervictims report that they experience greater internalizing and externalizing problems (e.g., Mitchell, Ybarra, & Finkelhor, 2007; Patchin & Hinduja, 2006; Wright, 2014b; Ybarra, Diener-West, & Leaf, 2007). When youths are involved in cyberbullying, they report more suicidal thoughts and suicide attempts when compared to uninvolved youths (Bauman, Toomey, & Walker 2013a). Experiencing or perpetrating cyberbullying increases youths' risk of mental health problems (Beckman et al., 2012) and psychiatric and psychosomatic problems (Sourander et al., 2010).

Many studies focused on the relationship between cyberbullying status (victim, bully) and the psychological and behavior consequences do not take into account youths' involvement in traditional forms of bullying. It is important to consider or control for involvement in traditional forms of bullying because these behaviors are highly correlated with cyberbullying (Williams & Guerra, 2007; Wright & Li, 2013b). Taking into account the high correlations between traditional bullying and cyberbullying, Bonanno and colleagues (2013) found that youths involved in cyberbullying experienced greater depressive symptoms and suicidal ideation. In similar researcher, Gradinger and colleagues (2009) and Perren et al. (2012) examined the conjoint effects of both cyberbullying and traditional bullying on youths' psychological and behavioral problems. They found that victims of both traditional face-to-face bullying and cyberbullying reported higher levels of internalizing symptoms when compared to children and adolescents who experienced only one type of victimization. Consequently, these findings indicate that being exposed to different types of bullying behaviors increases youths' experience of depression, anxiety, and loneliness. These findings further support the need for researchers to consider youths' involvement in both offline and online bullying to better understand these relationships and how to best intervene.

SOLUTIONS AND RECOMMENDATIONS

Cyberbullying is a global concern that needs attention by everyone in our communities.

It is important for school curriculum to include elements that teach youths about cyberbullying, digital literacy (i.e., the ability to effectively find, identity, evaluate, and use information obtained from digital content), and digital citizenship (i.e., using information technology in order to engage in society, politics, and government; Cassidy et al., 2012b). This curriculum should also incorporate the positive uses of digital technology, encourage the development of provictim attitudes, empathy, self-esteem, and social skills, and discourage normative beliefs that support bullying behaviors. Schools should also aim

to improve school climate by learning students' names, praising good behavior, and staying technologically up-to-date (Hinduja & Patchin, 2012). It might also be helpful for schools to develop a code of conduct that addressed appropriate digital technology use. Not only is the development of this code of conduct necessary but so is the enforcement of these policies.

Parents have an important role in helping to reduce cyberbullying. They should partner with educators from their children's school and increase their awareness and knowledge of digital technologies and negative online behaviors (Cassidy et al., 2012a; Diamanduros & Downs, 2011). In addition, parents should implement parental monitoring strategies (i.e., strategies parents use to mediate, monitor, and manage their children's relationship with digital media) that help to reduce their children's vulnerability to cyberbullying. They should keep an open dialogue with their children concerning appropriate digital technology use and behaviors. It is also important for parents to be aware of their own digital technology habits, as their children are always watching. Some parents might utilize mobile phones and texting while driving or use mobile phones during dinner or other special events. Consequently, it is important for parents to model appropriate online behavior and technology use to serve as role models for their children.

To fully address cyberbullying, there needs to be multi-pronged approaches and the coordination of multiple stakeholders. It might be difficult for schools and parents to effectively deal with cyberbullying as oftentimes adolescents do not report their experience with these behaviors. In addition, teachers and parents do not always have well-developed technology skills to help when adolescents report experiencing cyberbullying. Parents and teachers might not have the tools for providing effective strategies for dealing with cyberbullying when it occurs and preventing adolescents' exposure.

FUTURE RESEARCH DIRECTIONS

The aim of this chapter was to discuss cyberbullying and the role of different characteristics and risk factors these increase youths' involvement in these behaviors. The literature reviewed in this chapter indicates that there are some noticeable limitations and future directions for research. Anonymity is proposed to have a prominent role in youths' cyberbullying involvement. Despite this proposal, little attention has been given to how anonymous beliefs about the cyber context develop and how these beliefs relate to cyberbullying. It is also important for other research to focus on anonymous and non-anonymous forms of cyberbullying to better understand the motivations underlying these behaviors, and whether victims might experience different adjustment problems based on the form of cyberbullying that they experience. Such a focus is important as non-anonymous cyberbullying might be perpetrated by a known peer and have a stronger influence on youths' depressive symptoms than if the behaviors were perpetrated by someone who is unknown.

Additional research is needed to better understand the long-term impacts of cyberbullying involvement across different age groups. Many studies focus on early and late adolescents, with little attention given to elementary aged children or young adults (Madden et al., 2013; Ybarra et al., 2007). Examining cyberbullying among younger age groups might make it possible to understand the developmental trajectories of online and offline bullying involvement and could also shed light on the temporal ordering of these bullying behaviors. This research might provide valid conclusions about the age that increases youths' vulnerability to cyberbullying. Intervention and prevention programs could be developed which specific consideration to the specific age group identified as at the most risk for cyberbullying involvement.

CONCLUSION

The literature reviewed in this chapter highlights the need for continued research investigations on youths' cyberbullying involvement. The earlier research on cyberbullying aimed to understand the prevalence rates of these behaviors. Although this research provided a solid understanding of the extent of cyberbullying among youths, an understanding of the risk factors and consequences associated with involvement in cyberbullying was a needed focus. Many of the studies on the causes and consequences of cyberbullying utilize concurrent research designs, making it difficult to understand the long-term impact of these behaviors. Furthermore, most of these studies focus on individual level predictors, with more attention needed on contextual predictors, like parents, school, and peers. Ultimately, cyberbullying is a global concern, affecting all aspects of our society. Cyberbullying undermines our ethical and moral values, making it incredibly important that we unite and do our part to diminish youths' involvement in cyberbullying.

KEY TERMS AND DEFINITIONS

Anonymity: The quality of being unknown or unacknowledged.

Anxiety: A mental health disorder which includes symptoms of worry, anxiety, and/or fear that are intense enough to disrupt one's daily activities.

Collectivism: A cultural value that stressed the importance of the group over individual goals and cohesion within social groups.

Cyberbullying: Children's and adolescents' usage of electronic technologies to hostilely and intentionally harass, embarrass, and intimidate others.

Empathy: The ability to understand or feel what another person is experiencing or feeling.

Externalizing Difficulties: Includes children's and adolescents' failure to control their behaviors.

Individualism: The belief that each person is more important than the needs of the whole group or society.

Loneliness: An unpleasant emotional response to isolation or lack of companionship.

Normative Belief: Beliefs about the acceptability and tolerability of a behavior.

Parental Mediation and Monitoring: The strategies that parents use to manage the relationship between their children and media.

Parenting Style: The standard strategies that parents use in their child rearing.

Peer Attachment: The internalization of the knowledge that their peers will be available and responsive.

Peer Contagion: The transmission or transfer of deviant behavior from one adolescent to another.

Provictim Attitudes: The belief that bullying is unacceptable and that defending victims is valuable.

Social Exclusion: The process involving individuals or groups of people block or deny someone from the group.

Traditional Face-to-Face Bullying: The use of strength or influence to intimidate or physically harm someone.

What Is Cyberbullying?

Michelle F. Wright

Pennsylvania State University, USA & Masaryk University, USA

INTRODUCTION

Children and adolescents spend a great deal of time using and interacting through electronic technologies, including cell phones, gaming consoles, and the Internet (Madden, Lenhart, Duggan, Cortesi, & Gasser, 2013). They engage in and are exposed to different behaviors and content. Some of their involvement with electronic technologies includes many benefits, such as the ability to engage in quick communication with just about anyone, including friends and family, and having access to a multitude of rich information. Despite the many opportunities afforded by electronic technologies, many children and adolescents are exposed to risks, including identify theft, exposure to pedophiles, and viewing unwanted, gory, and/or graphic content. One risk associated with electronic technology usage among children and adolescents is cyberbullying. Cyberbullying occurs through electronic technologies, including gaming consoles, email, instant messaging, chatrooms, social media, and text messages via mobile phones. The attention given to cyberbullying incidences are due to the nature of electronic communications. Through electronic technologies, children and adolescents can remain anonymous, allowing them to harm their victims without experiencing repercussions. The rapid exchange of information and other content through electronic technologies is another concern. For example, a nasty image or video can spread within seconds through electronic technologies. Cyberbullying can also involve multiple bystanders who are also capable of resharing content. The literature in this chapter draws on research from various disciplines, including communication, computer science, education, media studies, psychology, social work, and sociology. Furthermore, the literature involves a variety of different research designs, including cross-sectional and longitudinal methodologies as well as qualitative and quantitative designs. The chapter is organized into the following six sections:

- (1) The first section provides definitions of cyberbullying, the technologies used to target others, the features of anonymity as applied to cyberbullying, and the prevalence rates of children's and adolescents' involvement in cyberbullying.
- (2) The second section describes the individual characteristics and risks associated with children's and adolescents' involvement in cyberbullying.
- (3) The third section details the role of parents and families in children's and adolescents' cyberbullying perpetration and victimization.
- (4) Similar to the third section, the fourth section explains the role of peers and school in children's and adolescents' cyberbullying involvement.
- (5) The purpose of the fifth section is to review literature on the psychological, behavioral, and academic consequences associated with cyberbullying involvement among children and adolescents.
- (6) The final section discusses future research and public policy recommendations related to drawing attention to cyberbullying as an important global health concern.

The Nature of Cyberbullying

As deliberately embarrassing or intimidating, cyberbullying involves the usage of modern electronic technologies to harm others using hostile and repetitive behaviors (Kowalski & Limber, 2007; Topcu, Erdur-Backer, & Aydin, 2008; Wolak, Mitchell, & Finkelhor, 2007; Ybarra, West, & Leaf, 2007). Cyberbullying is described as an extension of traditional face-to-face bullying, and it also includes elements of an imbalance of power between the bully and the victim as well as the incorporation of a technological component (Olweus, 1999; Topcu et al., 2008; Ybarra et al., 2007). These behaviors are repetitive, deliberate, and intentionally carried out by bullies with malicious intent (Grigg, 2010). Similar to the definition of traditional face-to-face bullying, cyberbullying can also involve repetition, although this component of the definition is more complex when the behavior involves electronic technologies. For instance, bullies might target victims once by posting humiliating videos but the victimization might continue when bystanders forward the content to others, either with malicious or benign intent. Similar to traditional face-to-face bullying, cyberbullying can also include behaviors with a face-to-face equivalent, such as spreading a rumor about a victim, harassment, physical threats, social exclusion, humiliation, gossiping about a victim to get others not to like the victim, and/or verbal insults. There are also physical forms of cyberbullying, like in traditional face-to-face bullying, which can include hacking. It can include making anonymous phone calls, theft of identity information by pretending to be someone else, distributing explicit videos via various websites, and harassment using instant messenger, social networking websites, and text messages through mobile phones (Wolak et al., 2007; Wright & Li, 2012; Ybarra & Mitchell, 2004). Other forms of cyberbullying involve happy slapping and flaming (Smith et al., 2008). Furthermore, cyberbullying can involve using various electronic technologies, with one study revealing that over half of their sample harmed others through instant messaging tools and social networking websites (Arslan et al., 2012).

Researchers have attempted to understand why children and adolescents engage in cyberbullying. One proposal is that new electronic technologies allow cyberbullies to hide their identities, furthering the power differential between the cyberbully and the cybervictim (Wright, 2013; Ybarra et al., 2007). Being anonymous through electronic technologies involves an imbalance of power between cyberbullies and cybervictims. Many children and adolescents who engage in cyberbullying choose to remain anonymous while perpetrating cyberbullying (Dehue, Bolman, & Vollink, 2008; Kowalski & Limber, 2007; Wright, 2014a; Ybarra & Mitchell, 2004). Another proposal relates to new electronic technologies' ability to allow the cyberbully to perpetrate frequent, repeated, and prolonged anonymous and/or non-anonymous harassment (Wolak et al., 2007; Wright, 2014a; Ybarra & Mitchell, 2004). Cyberbullying might be perpetrated because of the cyberbullies' ability to remain anonymous. Rates of anonymous cyberbullying vary from 12% in one study (Wright, 2014b) to 80% in another study (Arslan et al., 2012). Some research approaches the relationship between anonymity and cyberbullying differently. In this research, Moore et al. (2012) found that more anonymous forums triggered more cyberbullying incidences than less anonymous forums which require login details and passwords. Wright (2013; 2014a) found that when individuals felt more confidence in their ability to remain anonymous while using electronic technologies they engaged in more cyberbullying, especially when they could perpetrate cyberbullying anonymously. Anonymous cyberbullying intensifies cybervictims' negative feelings, including powerlessness (Dooley, Pyzalski, & Cross, 2009; Nocentini, Galmaestra, & Schultze-Krumbholz, 2010).

When an awareness of cyberbullying was gained by researchers, there were many studies conducted to understand how frequently children and adolescents were involved in these behaviors. In 2007, Wolak and colleagues (2007) conducted one of the earliest studies on cyberbullying in the United States. They

What Is Cyberbullying?

found that 50% of children and adolescents in their sample were victimized by cyberbullying. Lower prevalence rates have been found in other studies conducted on cyberbullying involvement in the United States. For instance, Kowalski and Limber (2007) found that 11% of their 3,767 sample from middle school (aged 11-14) were victimized by cyberbullying, 4% had cyberbullied others, and 7% were classified as cyberbullies-cybervictims. Similar estimates were found in a study of cyberbullying by Patchin and Hinduja (2006). Among their sample, they found that 29% reported that they were cybervictims, while 47% reported that they had witnessed cyberbullying at least once. More recent research revealed that 4.9% of children and adolescents in their sample ($N = 4,441$, 6-12th grade) were cybervictims within the past 30 days (Hinduja & Patchin, 2013).

Increasing evidence indicates that cyberbullying is not localized to one country. Instead, research has revealed that cyberbullying is a global concern. In one study, Cappadocia et al. (2013) found that out of their 1,972 sample of Canadian 10th graders, 2.1% perpetrated cyberbullying, 1.9% were cybervictims, and .6% were cyberbullies-cybervictims. Rates of cyberbullying involvement have also been examined in Australia as well. In this research, Campbell and colleagues (2012) found that 4.5% of their sample ($N = 3,112$; grades 6-12th) were victims of cyberbullying. Research has also documented cyberbullying involvement among European children and adolescents. Using a large sample of Swedish adolescents ($N = 22,544$; ages 15-18), Laftman et al. (2013) found that 5% of their sample were classified as cybervictims, 4% as cyberbullies, and 2% as cyberbullies-cybervictims. Rates were similar for cyber victimization in Ireland and Belgium such that 6% of Irish adolescents ($N = 876$; ages 12-17; Corcoran, Connolly, & O'Moore, 2012) and 6.3% of Belgian adolescents ($N = 1,042$, M age = 15.47; Heirman & Walrave, 2012) were classified as cybervictims. Prevalence rates of cyber victimization were much higher among Italian adolescents. For instance, Brighi and colleagues (2012) found that 12.5% of the 2,326 Italian adolescents in their sample were cybervictims. Cyber victimization was reported by 18% of Turkish adolescents in one sample, with 6% classified as cyberbullies ($N = 756$; 7th graders; Yilmaz, 2011). Another study found that 32% of adolescents in one Turkish sample ($N = 276$; ages 14-18) were cybervictims (Erdur-Baker, 2010).

Although slower to develop, some research has focused on cyberbullying involvement rates among children and adolescents in Asia. In one study, Huang and Chou (2010) found that 63.4% of their sample ($N = 545$) witnessed cyberbullying, 34.9% were cybervictims, and 20.4% were cyberbullies. Jang and colleagues (2014) examined rates of cyberbullying involvement among Korean adolescents, with findings revealing that 43% of adolescents in their sample ($N = 3,238$) were cybervictims or perpetrators of cyberbullying. Among a sample of Chinese adolescents ($N = 1,438$), Zhou et al. (2013) found that 34.8% were cyberbullies and 56.9% were cybervictims. Rates were similar among a sample of 1,676 13 through 17 year olds in Singapore such that 59.4% were cybervictims through Facebook and 56.9% were cyberbullies through Facebook (Kwan & Skoric, 2013).

Comparisons of prevalence rates are difficult as the researchers relied on different samples and measurement of cyberbullying. Regardless of the shortcomings associated with studies on prevalence rates of cyberbullying involvement, it is clear that cyberbullying is a concern for children and adolescents around the world. Such a consideration highlights the importance of studying cyberbullying by attempting to understand the risk factors related to children's and adolescents' involvement in cyberbullying as victims, perpetrators, and bystanders. Understanding risks factors associated with cyberbullying involvement can inform prevention efforts to reduce children's and adolescents' involvement in these behaviors.

Characteristics and Risk Factors Associated With Cyberbullying Involvement

3

After much of the research on the prevalence rates of cyberbullying involvement, many researchers directed their attention to understanding the characteristics and risk factors related to children's and adolescents' involvement in cyberbullying. Most of these earlier investigations focused on the role of demographic variables in cyberbullying perpetration and victimization. Age has been examined as a factor related to cyberbullying among children and adolescents. One study revealed that younger adolescents were at a greater risk of cyber victimization, while older adolescents were most frequently classified as cyberbullies (Ayas & Horzum, 2012). Physical forms of cyberbullying (e.g., hacking) were highest in middle school adolescents (Williams & Guerra, 2007). On the other hand, Wade and Beran (2011) found that 9th graders in their sample experienced the greatest risk of cyberbullying involvement when compared to adolescents in middle school. Such conflicting findings from studies focused on age indicated that this variable might be an inconsistent predictor of cyberbullying involvement. Gender is also another inconsistent predictor of cyberbullying involvement among children and adolescents. In particular, some researchers (Li, 2007; Ybarra et al., 2007) have found that boys self-reported more cyberbullying perpetration when compared to girls, with some research revealing that girls experienced more cyber victimization in comparison to boys (Hinduja & Patchin, 2007; Kowalski & Limber, 2007). In contrast, some researchers (e.g., Dehue et al., 2008; Pornari & Wood, 2010) have found that girls were more often the perpetrators of cyberbullying in comparison to boys, while boys were much more likely to be victims of cyberbullying (e.g., Akbulut, Sahih, & Eristi, 2010; Erdur-Baker, 2010; Huang & Chou, 2010). On the other hand, some researchers have found no gender differences in children's and adolescents' cyberbullying involvement (Beran & Li, 2005; Wright & Li, 2013b).

Researchers have focused on the associations between children's and adolescents' involvement in face-to-face bullying and cyberbullying involvement. This literature has revealed that there are positive associations between the perpetration of offline and online bullying, as well as between face-to-face bullying victimization and cyber victimization (Cappadocia et al., 2013; Mitchell et al., 2007; Steffgen, Kong, Pfetsch, & Melzer, 2011; Fanti, Demetriou, & Hawa, 2012). Longitudinal research evidence also suggests that face-to-face victimization is a long-term risk factor for adolescents' involvement in cyberbullying (Wright & Li, 2012).

Some research has been conducted on other characteristics and risk factors associated with cyberbullying involvement among children and adolescents. One risk factor for cyberbullying involvement is internet usage. In this research, cyber victims and cyberbullies typically report higher rates of chatting, emailing, blogging, gaming, and sending instant messages when compared to uninvolved children and adolescents (Smith et al., 2008; Ybarra & Mitchell, 2004). To explain the association between greater internet usage and cyberbullying involvement, Ybarra and colleagues (2007) proposed that cyber victims and cyberbullies are more likely to disclose personal information online, which worsens their exposure to online risks, such as cyberbullying. Thus, frequent internet usage increases children's and adolescents' willingness to disclose private information through electronic technologies. Higher normative beliefs concerning both traditional face-to-face bullying and cyberbullying were also related to cyberbullying perpetration among adolescents (Ang, Tan, & Mansor, 2010; Burton, Florell, & Wygant, 2013; Wright & Li, 2013a). Such findings indicate that cyberbullies view bullying behaviors as normal, which contributes to their perpetration of these behaviors. Defined as children's and adolescents' beliefs that bullying is unacceptable and that defending victims is valued, provictim attitudes are also related to cyberbullying perpetration. In particular, Elledge and colleagues (2013) found that holding lower levels of provictim attitudes were associated with greater cyberbullying perpetration. Other research has revealed that low

self-control, less empathy, and moral disengagement are also contributors to cyberbullying perpetration (Jang et al., 2014; Robson & Witenberg, 2013).

Few studies have focused on the longitudinal risk factors related to cyberbullying involvement. Utilizing a longitudinal design, Fanti and colleagues' (2012) study revealed that media violence exposure, along with callous and unemotional traits, predicted cyberbullying perpetration one year later. Media violence exposure was also a risk factor associated with cyber victimization. Current research has indicated that perceived stress from parents, peers, and academics also increases cyberbullying perpetration one year later among adolescents (Wright, in press). Considering each of the studies examined in this section, it is clear that there are a variety of individual characteristics and risk factors which make children and adolescents vulnerable to cyberbullying involvement. Other research has focused on the role of other individuals in children's and adolescents' involvement in cyberbullying. Parents and families have also been examined as having a role in children's and adolescents' cyberbullying perpetration and victimization.

The Role of Parents and Families

Parental monitoring and parenting styles have been examined in relation to children's and adolescents' involvement in cyberbullying. Mason (2008) found that 30% of adolescents in his sample utilized the Internet for three hours or more daily, with 50% of these adolescents reporting that their parents monitored their activities. Even when parents do monitor their children's online activities, they are usually not effective because some parents lack technological skills and many do not follow-up on the strategies that they have implemented. In addition, many parents in one sample reported that they were not certain of what their children did online and they were less certain on how to discuss the topic of online activities with their children (Rosen, 2007). McQuade and colleagues (2009) found similar results, with 93% of parents indicating that they set rules of the internet, although 37% of their children reported that they were not given specific rules regarding their internet use. Because parents are not able to engage in an active and ongoing dialogue with their children about online activities and considering that experiencing online risks is almost inevitable for children, it is not likely that some children have the skills necessary to effectively deal with problematic situations that arise online. A handful of studies has focused on parents as serving a protective function in mitigating their children's involvement in cyberbullying. Adolescents who believed that their parents would punish them for engaging in cyberbullying engaged in less of these behaviors (Hinduja & Patchin, 2013). Wright (2015b) also found that high parental mediation reduced adolescents' risk of cyberbullying involvement and the negative adjustment difficulties.

Another line of research focuses on the associations between family characteristics and children's and adolescents' cyberbullying involvement. In this research, Ybarra and Mitchell (2004) revealed that lower caregiver monitoring and poor emotional bonds with caregivers were risk factors associated with cyberbullying. They did not find evidence that family income, parental education, and caregiver status (single or married) were related to cyberbullying perpetration or cyber victimization. On the other hand, Aricak and colleagues' (2012) study revealed that parental unemployed increased children's and adolescents' risk of being involved in cyberbullying. Neglectful parenting is also a risk factor associated with cyberbullying perpetration and cyber victimization. In particular, Dehue and colleagues (2012) found that victims and perpetrators of cyberbullying were more likely to report that their parents engaged in neglectful parenting styles when compared to uninvolved children and adolescents. Similarly, their study also indicated that authoritarian parenting style increased children's and adolescents' risk of cyber victimization. More attention should be given to the role of parents and families in children's and adolescents' cyberbullying involvement.

The Role of Schools and Peers

Once children enter formal schooling, they spend most of their time in such settings until they graduate from high school or college. Consequently, some researchers have directed their attention to the linkages of peers and schools to children and adolescents' bullying involvement. Although schools' role in cyberbullying involvement is a bit complicated, some research has focused on how schools, particularly teachers and school climate, impact children's and adolescents' cyberbullying involvement. In one study, many teachers perceived the impact of overt forms of traditional face-to-face bullying as much worse than covert forms of bullying, like relational aggression and some forms of cyberbullying (Sahin, 2010). Cyberbullying and schools' involvement in these incidences is further complicated because many situations involving cyberbullying occur outside of school through electronic technologies. This makes it difficult for teachers to know about such incidences and for them to intervene or provide support to the victim. Additionally, many teachers have not been properly trained on how to deal with and recognize cyberbully behaviors as well as the risk factors associated with these behaviors, furthering hindering schools' ability to deal with these behaviors. Cassidy and colleagues (2012a) found that some of the Canadian teachers in their sample were unfamiliar with some of the newer electronic technologies. Their lack of knowledge made it difficult for them to deal with cyberbullying, even if a victim came to them for help. Many teachers are more willing to promote face-to-face bullying prevention than cyberbullying prevention programs (Tangen & Campbell, 2010). It is important for teachers, school staff, and administrators to understand more about cyberbullying as children's and adolescents' involvement in these behaviors can negatively influence the learning process.

Cybervictims and cyberbullies view their schools and teachers more negatively than uninvolved children and adolescents (Bayar & Ucanok, 2012). A negative school climate and lower school commitment increase cyberbullying perpetration at schools (Ybarra & Mitchell, 2004; Williams & Guerra, 2007). Another problem inhibiting schools' ability to deal with cyberbullying is that there are few implemented policies and programs, even when teachers were concerned with these behaviors (Cassidy, Brown, & Jackson, 2012b). It is important that teachers are concerned about cyberbullying and understand how to prevent it. Teachers' motivations for learning about cyberbullying and their self-efficacy for believing in their ability to deal with these behaviors decreased from elementary school to middle school. Such a finding from Cassidy and colleagues (2012b) is surprising because cyberbullying typically increase in the middle school years (Ybarra et al., 2007). Teachers are more likely to protect students from cyberbullying when they develop awareness of these behaviors (Elledge et al., 2013).

Another feature of the school environment are children's and adolescents' peers who serve as indicators of social norms, including acceptable and unacceptable behaviors. Festl and colleagues (2013) examined the role of peers in adolescents' cyberbullying involvement. Their findings revealed that one of the best predictors of cyberbullying involvement were classrooms in which the highest incidences of cyberbullying occurred. In addition, adolescents who believed that their friends perpetrated cyberbullying were more likely to perpetrate these behaviors as well (Hinduja & Patchin, 2013). Some research has focused on the quality of peer relationships to understand children's and adolescents' involvement in cyberbullying. In particular, Burton and colleagues (2013) found that higher levels of peer attachment were related negatively to cyberbullying perpetration and cyber victimization. In addition, being rejected by one's peers was also related to cyberbullying, even after controlling for face-to-face victimization (Wright & Li, 2013b). Research has also revealed that cyberbullying perpetration might be used to boost adolescents' social status among their peer group. For example, Wright's (2014b) study suggested that higher levels of perceived popularity, a reputational type of popularity usually linked to traditional

face-to-face bullying perpetration, increased adolescents' cyberbullying perpetration six months later. In another study, Wright (2015b) found that friends served a protective function in reducing adolescents' cyber victimization and the negative adjustment difficulties associated with this experience. Friends might discuss technology skills, online safety, and reinforce appropriate online practices (e.g., not sharing passwords, discussing personal information with strangers) and behaviors.

Psychological, Behavioral, and Academic Difficulties

Researchers, educators, and parents are particularly concerned about the psychological, behavioral, and academic difficulties associated with adolescents experiencing and/or perpetrating cyberbullying. Cybervictims reported lower global happiness, school happiness, school satisfaction, school satisfaction, family satisfaction, and self-satisfaction when compared to uninvolved adolescents (Navarro et al., 2013). Similarly, researchers (e.g., Beran & Li, 2005; Dehue et al., 2008; Patchin & Hinduja, 2006) have found that cybervictims felt greater levels of anger, fearfulness, and sadness in comparison to uninvolved children and adolescents, as well as more emotional and peer problems. Perpetrators and victims of cyberbullying reported internalizing difficulties, such as depression and anxiety, and externalizing difficulties, including drug and alcohol use as well as violence (Arslan et al., 2012; Li, 2007; Patchin & Hinduja, 2012; Ybarra et al., 2007). Cyberbullying involvement is also linked to problems in school. In one study, Wright (2015a) examined the longitudinal associations between school functioning and cyberbullying involvement. She found that cyberbullying perpetration and cyber victimization were each associated with poor academic performance, absenteeism, and school behavioral problems (e.g., classroom disruptions) one year later. Some researchers have focused on psychological and behavioral difficulties associated with the joint effects of children's and adolescents' involvement in traditional face-to-face bullying and cyberbullying. Victims who were victimized by both traditional face-to-face bullying and cyberbullying reported more internalizing difficulties when compared to adolescents who experienced only one type of victimization (Grading, Strohmeier, & Spiel, 2009; Perren, Dooley, Shaw, & Cross, 2010).

The bulk of the research on the psychological, academic, and behavioral difficulties associated with children's and adolescents' cyberbullying involvement do not control for traditional face-to-face bullying involvement. Controlling for these variables is important as there are strong correlations between cyberbullying involvement and traditional face-to-face bullying involvement. To this end, Bonanno and colleagues (2013) examined cyberbullying perpetration and cyber victimization in relation to depressive symptoms and suicidal ideation. After including face-to-face bullying and victimization in the same model, they still found associations between these variables. However, Brighi and colleagues (2012) did not find a relationship between cyber victimization and loneliness or self-esteem, after accounting for traditional face-to-face bullying victimization.

RECOMMENDATIONS

There are a variety of gaps in the cyberbullying literature, which need to be investigated through future research. One recommendation is that follow-up research needs to focus on understanding more about the concept of anonymity as applied to cyberbullying. Anonymity is not only a component of cyberbullying, but anonymous forms of traditional face-to-face bullying can occur as well. For example, a nasty note can be slipped into a peer's locker anonymously. Thus, research should be conducted to understand

differences in children's and adolescents' conceptualizations of anonymous acts in the cyber context and the offline world. There are few longitudinal studies conducted on cyberbullying involvement. In future research, longitudinal designs should be utilized to examine both traditional face-to-face bullying and cyberbullying involvement from childhood into late adolescence or even emerging adulthood. Investigations focused on the developmental trajectory of bullying involvement in both social contexts are important as much of the research on cyberbullying does not take into account previous levels of traditional face-to-face bullying, although these variables are strongly correlated (Wright & Li, 2013a; Ybarra et al., 2007). Researchers are beginning to understand that attacks which occur in cyberspace might be just as powerful as face-to-face attacks. Our communities need to recognize this threat and devote time to dealing with it, as it affects everyone. Cyberbullying will probably not disappear anytime soon, due to our increasing reliance of electronic technologies. Therefore, we all must stand united in our efforts to reduce or prevent cyberbullying.

How Theoretical Frameworks Inform the Understanding of the Relationship Between Gender and Cyberbullying

INTRODUCTION

Over the past two decades, bullying has received considerable attention, with scholars, educators, parents, and youths expressing their concerns regarding bullying at school. While studies suggest that bullying is relatively common in elementary, middle, and high schools, bullying also occurs outside of schools. The Internet, as well as other forms of technology, provide a platform that allows bullying to extend beyond face-to-face peer interaction. Scholars identify this form of bullying as *cyberbullying*. Cyberbullying refers to intentional, aggressive behaviors that are perpetrated through mediated communication, such as email, text messages, social media, or other online websites (Sticca & Perren, 2013). Cyberbullying not only affects school-age youth and adolescents, as recent literature suggests that technological advances have also contributed to an increase in workplace cyberbullying among adults (D'Souza, Forsyth, Tappin & Catley, 2018; Vranjes, 2018).

While both bullying and cyberbullying have gained national attention, research remains uncertain regarding the link between gender and various forms of bullying. Seals and Young (2003) suggest that like most crime, males are more likely than females to both perpetrate and be the victim of bullying. Yet, other researchers argue that both males and females are equally likely to engage in bullying, but there are gender differences in the ways in which boys and girls engage in bullying (Day & Kahle, 2014). Other research specifically focuses on gender differences in regard to cyberbullying perpetration and victimization. For example, Li (2006) found that among a sample of 256 youths, 22% of males reported engaging in cyberbullying as perpetrators, compared to 11.6% of female youths. However, there was little difference between male (25%) and female (25.6%) youths in relation to being the *victim* of cyberbullying (Li, 2006). More recently, using an online questionnaire to ask youths about their experiences with cyberbullying (N=208), Wong, Cheung, and Xia (2018) found that compared to female youths, males were more likely to be both the perpetrators *and* victims of cyberbullying. While these studies are valuable contributions to research on cyberbullying, they also suggest that research is inconclusive concerning the relationship between gender and cyberbullying perpetration and victimization.

Scholars recognize the importance of understanding the relationship between gender and various forms of bullying because there may be unique consequences for male and female victims of cyberbullying. For example, drawing from a sample of 1,222 youths across 15 schools in the United States, Carbone-Lopez, Esbensen, and Brick (2010) found that girls tended to experience a broader range of consequences related bullying than their male counterparts, including more severe psychological and health problems.

DOI: 10.4018/978-1-7998-3479-3.ch028

The authors also found that being the victim of indirect or relational bullying had a negative effect on girls' self-esteem, while for boys, this form of bullying was not associated with variations in self-esteem.

Therefore, in this article, the authors argue that to better (1) help individuals cope with their experiences with cyberbullying victimization and (2) prevent individuals from engaging in cyberbullying, scholars, educators, and policymakers need to better understand patterns and trends associated with online bullying. This article contributes to research on gender and cyberbullying by merging insights from criminology, sociology, and gender studies to review prior literature on bullying and more specifically, cyberbullying. Additionally, the authors present how theoretical perspectives, including the "doing gender" perspective and an intersectional approach may help shape our understanding regarding the relationship between gender and cyberbullying. Following this, the authors consider implications for policy development and future research.

BACKGROUND

Scholars identify bullying as intentional, repeated actions meant to harm a victim and perpetuate an inequity of power (Olweus, 1991). Traditional forms of bullying take place in-person, typically occurring in a specific location, such as schools and workplaces. Bullying encompasses both overt and relational forms of abuse and harassment manifested in a multitude of ways, including physical altercations, taunts, gossip, or exclusion from specific groups or certain activities that cause relational damage (Thomas, Connor, & Scott, 2014). Research on traditional bullying distinguish that these actions occur without the assistance of technology; the harassment is often face-to-face or, in the case of gossip, circulated directly from person to person.

Over the last decade, bullying has evolved alongside the technological revolution of computers, cell phones and other communication devices. Deliberate, overt or covert behaviors perpetrated through digital technology is referred to as *cyberbullying* (Mendez, Bauman, & Guillory, 2012). Like traditional forms of bullying, cyberbullying also takes several forms including sending hurtful or threatening text messages or emails, spreading rumors through emails and private messaging, forwarding private pictures to unintended recipients, and posting derogatory comments and pictures on social media. Cyberbullying may take place anonymously or the bully and victim may know each other as peers or even co-workers (Vranjes et al., 2018).

The incidence of cyberbullying has increased as the Internet and communication technologies have grown (Aivazpour & Beebe, 2018). Following this, there has been a surge of research on cyberbullying (Zych, Farrington, & Llorent, 2018). One example is Carter and Wilson (2015) who surveyed a sample of 367 adolescents from the Midwest, asking about their participation in cyberbullying. The authors found that among their sample, 17% reported that they had been the victim of cyberbullying. Carter and Wilson concluded that the already high prevalence of cyberbullying would continue to rise with technological advances. Another example is Wilton and Campbell (2011) who explored the reason why youths engage in cyberbullying. They found that adolescents were more likely to partake in the virtual harassment of their peers for reasons of emotional self-satisfaction. The authors argued that virtual or online bullying may become a more popular alternative to traditional bullying as it allows perpetrators to disassociate from "real" life and provides bullies with a sense of anonymity.

Recently, Gofin and Avitzour (2012) argue the Internet has the ability to connect both friends and complete strangers, and it may blur the lines between actions and direct negative outcomes. Consequently, cyberbullies may not perceive their online behaviors as bullying because of the mediated communication

between online bullying and victim (Gofin & Avitzour, 2012). Therefore, research may be underestimating the prevalence of cyberbullying if the cyberbullies themselves do not realize they are engaging in this problematic behavior.

Consequences Associated with Bullying and Cyberbullying Victimization

Studies consistently find that there are numerous negative consequences associated with being the victim of bullying. For example, being the victim of bullying is associated with lower grades (Konishi, Hymel, Zumbo, & Li, 2010) and avoidance behaviors at school (Hutzell & Payne, 2012). Other studies suggest that victims of bullying are more likely to experience mental health issues than their peers who were not bullied, including higher rates of depression, loneliness, and anxiety (Nishina, Juvonen, & Witkow, 2005). Victims of bullying often have low levels of self-efficacy and more psychosocial adjustment problems than individuals who were not bullied (Nansel et al., 2004). Drawing from longitudinal data, Radu (2018a) found that victims of childhood bullying were more likely to engage in subsequent violent behavior than their non-bullied peers. Bullying may also have a negative effect on educational outcomes, as victims of bullying tend to have higher rates of dropping out of high school compared to students who had not experienced being bullied (Cooper & Nickerson, 2013).

There are numerous adverse mental health consequences associated with cyberbullying victimization (Abreu & Kenny, 2018), including increased feelings of anxiety, depression, and feelings of loneliness, and lower levels of self-esteem (Motswi & Mashegoane, 2017). Victims of cyberbullying often report emotional issues, such as anger, sadness, and depression (Balakrishnam, 2018). In a study comparing cyberbully victims with non-victims, Gorzig (2016) found that victims of cyberbullying were more likely than non-victims to view suicide and self-harm related materials on the Internet. Additional studies suggest that workplace cyberbullying has severe consequences for victims, as Kowalski, Toth, and Morgan (2018) found that victims of cyberbullying reported lower levels of self-esteem and higher levels of social anxiety and depression compared to those who had been the victim of workplace cyberbullying. Motswi & Mashegoane (2017) argue that the mobility of cyberbullying means that individuals can be bullied in several different contexts, which could include home, school, and the workplace, which may increase the risk of long-term negative consequences. Additionally, the negative impact of cyberbullying victimization may be exacerbated by the large audience that the web provides (Slonje & Smith, 2008), meaning there are often bystanders or witnesses of cyberbullying incidents. Online bystanders have the potential to defend or support the bully victim, but research suggest that bystanders may also reinforce or join in cyberbullying the target (Shultz et al., 2014).

Sociological and criminological theories are useful in explaining problematic behaviors, such as experiences with victimization. In the following section, the authors review the value of considering West and Zimmerman's (1987) "doing gender" framework and Crenshaw's (1989) intersectionality to better understand the relationship between gender and cyberbullying.

MAIN FOCUS OF THE CHAPTER

Doing Gender, Bullying, and Cyberbullying

In West and Zimmerman's (1987) seminal work, they argued that gender is a social construct, a routine accomplishment that is embedded in everyday interactions. They argued that gender is produced and

reproduced by social interaction and people are judged in terms of how consistent they are with social beliefs about gender. It is further argued that gender is a situated accomplishment in terms of “normative” expectations for a particular sex category (West & Zimmerman, 1995). West and Zimmerman’s (1987) “doing gender” developed from Goffman’s (1976) concept of gender display, which maintains that displays of gender are highly conventionalized behavioral-exchanges. Within these social exchanges, the presence or absence of symmetry can establish either deference or dominance. Goffman argued that gender is a socially scripted dramatization of the culture’s idealization of feminine and masculine nature, suggesting that gender permeates all social situations; therefore, avoidance of being judged as either masculine or feminine is unavoidable. Gender display focuses on the behavioral aspects of being a woman or man, opposed to biological differences (Goffman, 1976). Drawing from Goffman’s ideas, West and Zimmerman also argued that “doing gender” is unavoidable because gender is an ideological device which produces, reproduces, and legitimates individuals’ choices, as people are often judged regarding how consistent their behaviors are with social standards of their gender. The social arrangements based on one’s sex category are viewed as legitimate ways of organizing social life—men doing dominance and women doing deference—which creates and maintains hierarchical arrangements through what are considered natural or biological differences (West & Zimmerman, 1987).

Understanding how youth “do gender” is important to the study of bullying and cyberbullying because studies consistently find that gender is linked to bullying in several ways. Crick and Grotpeter (1995) found that girls were more likely than boys to engage in covert or relational bullying, findings that are supported by a range of other studies (e.g., Cullerton-Sen & Crick, 2005; Wang, Iannotti, & Nansel, 2009). Crick and Grotpeter (1995) argued that girls’ use of relational bullying tended to be focused on damaging reputations rather than inflicting physical harm, while male students were more likely to be involved in direct, overt, or physical bullying. SooHoo (2009) found that girls were more likely to utilize relational bullying as they attempted to maintain their social status or lower a peer’s status. While Connell (2005) argued that male-perpetrated violence towards other males may be used to display one’s masculinity. Boys and young men may attempt to gain prestige and a positive “tough guy” image by engaging in physical violence towards their male peers. Using in-depth interviews and comparison groups, Messerschmidt’s (2000) reported similar findings. He discovered that masculine identities were constructed through interaction with the home and school, and different “masculine resources” are available for different individuals depending on their circumstances. Messerschmidt found that schools were environments where young men constructed violent masculinities by victimizing their weaker male peers.

Other studies suggest that differences in type of technology use by gender may contribute to both the acceptance and perpetration of cyberbullying. Drawing from a three-wave longitudinal study of adolescents (N = 3,000), Barlett and colleagues (2018) found that female adolescents tended to spend more time on social media websites both on their phones and on their computers than their male peers, and they were more likely to use blogs to express their feelings than male adolescents. However, the authors found that even though female youth spent more time on social media websites than male youth, the male participants were more likely to have positive cyberbullying attitudes and engage in cyberbullying perpetration than their female counterparts. This suggests that while there may be gender differences in technology medium and use, the relationship between gender, technology, and cyberbullying perpetration is complex and additional research is needed to provide a more nuanced understanding of this relationship.

Additionally, there is disagreement within academic literature whether gender is a significant factor in cyberbullying perpetration and victimization. Motswi and Mashegoane (2017) found in a study of 324 secondary school students in the Limpopo Province, Africa that there were more female students affected by cyberbullying (11%) than males (4%). Other studies suggest that suggests that girls tend to

engage in cyberbully to impress boys or to gain male attention by taking out “competitors,” and girls are more likely to insult appearances than resort to physical violence (Goddard, 2008). Drawing from a two-wave panel survey among 1,817 high school students in southwest Germany, Festl and Quandt (2016) found that compared to their female counterparts, male participants were more likely to participate in various forms of cyberbullying as the cyberbullies. Additionally, boys reported overall higher frequencies of cyberbullying victimization experiences than their female peers, including being insulted on a public website, having an embarrassing picture or video of themselves posted online, and receiving a message from someone using a fake identity. These discrepancies regarding the association between gender and cyberbullying suggest that this relationship needs to be further addressed. “Doing gender” varies across time and context; therefore, by considering different ways in which “doing gender” may vary will help scholars provide a more nuanced understanding regarding the relationship between gender and cyberbullying.

Intersectionality, Bullying, and Cyberbullying

Crenshaw’s (1989) *intersectionality* is a theoretical framework that allows researchers to consider experiences of multiple dimensions of individuals’ lives. An intersectional approach emphasizes that experiences with victimization may vary based on individuals’ social identities. That is, instead of looking at gender, racial, and sexuality-based categories as having separate and distinct effects on individuals’ experiences, an intersectional approach stresses that individuals’ social identities are experienced simultaneously (Choo & Ferree, 2010; Miller, 2006; Núñez, 2014). For example, Miller’s (2006) research on young African American women’s experiences with victimization both within and external to the school helped place a dually marginalized group at the center of research. Miller’s approach gave a voice to a marginalized group, whose experiences with victimization were largely overlooked.

Recently, Radu (2018b) argued that relatively few studies on bullying or cyberbullying examine the combined effects of gender, race, and sexuality on forms of bullying and outcomes associated with bullying. This problematic because youth who face intersecting categories of oppression, such as being a student of color and identifying as gay, lesbian, bisexual or transgender, may be at a higher risk for being targeted for both bullying and cyberbullying. In fact, a recent student survey administered to nearly 80,000 public school students found that two of the top three reasons students believe they are bullied are because of their race or skin color and because their peers perceive them as being gay (Youth Truth, 2016). This suggest that more research is needed that explicitly uses an intersectional approach to understand the bullying and cyberbullying victimization experiences of multiple-marginalized groups of youth.

IMPLICATIONS FOR POLICY AND DIRECTIONS FOR FUTURE RESEARCH

Most agree that schools are responsible for developing policies on both bullying and cyberbullying, including additional training for teachers and anti-cyberbullying initiatives (Macaulay, Betts, Stiller & Kellezi, 2018). Policies prohibiting the use of the school’s Internet system for cyberbullying behaviors are somewhat common across schools (Snakenborg, Van Acker, & Gable, 2011), and scholars continue to look for unique ways to recommend that schools address problems with cyberbullying. One example is Diamanduros and Downs (2011) who argued that within schools, the library media specialist is in a unique position to bring more awareness to students, faculty, and staff about ways to combat cyberbul-

lying. They argue that school library media specialists may be able to address cyberbullying in schools by establishing policies and promoting awareness to prevent online bullying.

Hoff and Mitchell (2009) agree that the school should be at the center of the solution to address youths' involvement with cyberbullying, but they recommend a more collaborative approach among educators, parents, and youths. They argue that first, students and their parents need to be educated about the dangers of cyberspace to protect youths from online victimization. However, Hoff and Mitchell also note that a limitation of this approach is it places most of the burden on those targeted by cyberbullying, rather than addressing the behaviors of the perpetrators. Moving forward, they recommend that it may be helpful to have students themselves engaged in the development of policies and practices to respond to cyberbullying because they may understand it better than school faculty, staff, and administrators.

Other studies also point to families as agents to help prevent cyberbullying. Recently, Radu, Sobba, and McManus (2017) argue that quality parent-child relationships and open communication may help deter bullying. Parents should both encourage their children to report bullying and online behaviors and understand what to do if they see bullying both in schools and online. Additionally, Beale and Hall (2007) suggests that in order to prevent cyberbullying, parents need to support schools' efforts to address cyberbullying, including talking to children about the appropriate use of the Internet, monitoring their children's Internet use, and staying up-to-date with trends in digital communication (e.g., acronyms and emojis). They also recommend that parents work in collaboration with teachers and law enforcement to create cyberbullying programs (Beale & Hall, 2007). Beale and Hall's ideas are supported by more recent studies that suggest that bridging families and schools may help deter forms of bullying. For example, Axford et al., (2015) suggest that parental involvement in school-based bullying programs may increase teachers' awareness of incidents of bullying through parental reporting. Consequently, teachers and/or other school administrators cannot address cyberbullying incidents if they are not made aware about the problematic behaviors occurring online.

While these studies point to directions for further development of bullying and cyberbullying prevention programs, the authors argue that families, schools, workplaces, and communities may be more successful in developing policies and programs to deter cyberbullying if they focus on gender differences associated with these problematic behaviors. For example, what could families and schools do to help youths construct positive masculinities that do not rely physically aggressive behaviors? What approaches would be useful for helping increasing girls' self-esteem, so they do not rely on putting their peers down in order to gain social status? What can school faculty, staff, and administrators do to build a more inclusive school environment for youths who do not "fit in" with their peers? How can workplaces develop information technology (IT) departments specifically designed to combat unethical and aggressive online behaviors? These questions point to directions for future research and policy development.

CONCLUSION

This article explored gender differences in bullying and cyberbullying using an interdisciplinary approach by merging research from a variety of disciplines. It also addressed commonalities and differences between bullying and cyberbullying and suggested how to utilize theory to better understand gender differences associated with cyberbullying. This was followed by a review of how cooperative forces among individuals, communities, and social institutions may be able deter both bullying and cyberbullying behaviors. Following current research, the authors argue that collaborative efforts among schools, families, workplaces, and communities may be most effective for deterring bullying that occurs within

various contexts and online. Additionally, considering how individuals “do gender” and how gender intersects with individuals’ other social identities may help in the development of future policies and programs that address problematic behaviors among both youths and adults.

KEY TERMS AND DEFINITIONS

Bully: An individual who asserts dominance by engaging in repeated and aggressive behaviors towards an individual or individual(s).

Bully Victim: An individual who has been the target of harmful and aggressive behaviors.

Bullying: Intentional, repeated actions meant to harm a victim and perpetuate an inequity of power between the bullying and victim(s).

Cyberbullying: Aggressive behaviors that are perpetrated intentionally through mediated communication, such as email, text messages, social media, or other online websites.

Doing Gender: A perspective that suggests that gender is a social construct, a routine accomplishment that is embedded in everyday interactions.

Gender Display: The behavioral aspects of being a woman or man, opposed to biological differences between the sexes.

Intersectionality: A theoretical framework that considers multiple dimensions of individuals' lives, emphasizing that experiences may vary based on the overlapping nature of individuals' social identities.

Workplace Cyberbullying: Aggressive online behavior that is intentionally perpetrated between or among co-workers.

The Human Rights–Based Approach to Combat Cyberbullying Against Women and Girls

Sabrina Ching Yuen Luk

Nanyang Technological University, Singapore

INTRODUCTION

Cyberbullying against women and girls has become more prevalent when the Internet and mobile technologies become more widely available and accessible in terms of cost. The use of information and communications technologies (ICTs) by an individual or group to intentionally embarrass, taunt, harass, threaten, torment or humiliate a woman or a girl takes places in blogs, on chat rooms or social networking sites, through emails, voice mails, texting, instant messaging, photo or video-clip sharing. This has led to multifaceted consequences that negatively affect the woman's or the girl's self-esteem, physical and mental health, behaviours, relationship with other people and motivation to live, study and work. At present, actions taken to combat cyberbullying against women and girls remain inadequate because of insufficient attention and support and deeply held prejudices against women. In order to have an in-depth investigation into this issue, this study examines what cyberbullying is, its causes and consequences, and a human rights based approach to combat cyberbullying against women and girls.

BACKGROUND

Women and girls have long been victims of physical violence and sexual violence. According to the 2013 Global Estimates published by World Health Organization, about 1 in 3 (35 percent) of women worldwide “have experienced either physical and/or sexual intimate partner violence or non-partner sexual violence in their lifetime” (World Health Organization, 2017). Violence against women and girls “is prevalent in every society in the world” (UNiTE, n.d.) that it “cuts across boundaries of wealth, race and culture” (UNiTE, n.d.). It “is rooted in gender-based discrimination and social norms and gender stereotypes that perpetuate such violence” (UN Women, n.d.). Although some measures have been taken by governments across countries to end such violence, the continued prevalence of violence against women and girls is “yet to be tackled with all the necessary political commitment, action and resources” (UNiTE, n.d.).

Over the past decade, cyberbullying has become a new form of violence against women and girls. Cyberbullying refers to the use of information and communications technologies (ICTs) by an individual or group to intentionally embarrass, taunt, harass, threaten, torment or humiliate a person through a range of hostile and aggressive behaviours, such as trolling, stalking or doxing. Trolling disturbs or harms another person by posting irrelevant, unpleasant and offensive messages online while stalking causes a person to fear for his or her safety or suffer other emotional distress by willfully tracing, following and monitoring

DOI: 10.4018/978-1-7998-3479-3.ch029

such person online without his or her consent. Doxing involves revealing identifiable information about someone online without his or her consent, including one's real name, home address, phone number and email address (Amnesty International, 2018, p.29). Over the past decade, cyberbullying has become more prevalent when the Internet and mobile technologies become more widely available and accessible in terms of cost. It takes places in blogs, on chat rooms or social networking sites such as Facebook and Twitter. It also takes places through emails, voice mails, texting, instant messaging, photo or video-clip sharing. "As the bullying process continues, the frequency and intensity of the aggressions tend to increase" (Forssell, 2018). Cyberbullying involves an imbalance of power between the perpetrator and the victim due to the perpetrator having the expert knowledge of the Internet (Ybarra and Mitchell, 2004), the anonymity of the perpetrator, the aggression directed towards the victim and the fear created in the victim (Betts, 2016, pp.15-16). Cyberbullies are able to "hide their identities by using screen names and well-hidden internet protocol addresses, leaving the target vulnerable and unsettled" (Hoff and Mitchell, 2009, p.653). While most of the time the identities of cyberbullies are unknown to the victims, cyberbullies can be someone from the victim's social circle, such as a close friend, a classmate, a co-worker, a current or former boyfriend or girlfriend. In the virtual world, the removal of geographical and time constraints allows the acts associated with cyberbullying to be witnessed by an unlimited audience (Betts, 2016, p.39). This has the effect of the victim "experiencing repeated humiliation because although the act is not repeated the negative experience associated with it is" (Betts, 2016, p.38).

In recent years, cyberbullying has become alarmingly common among women and girls. A study that examined cyberbullying risk among teenagers in the United States (U.S.) found that adolescent females were more at risk for cyberbullying than adolescent males (Navarro and Jasinski, 2012, pp.89-90). A study that examined cyberbullying among 1,928 German, Dutch and Thai adolescents found that girls were more likely than boys to be victims while boys were more likely than girls to be bullies (Wachs et al., 2015). Another study that examined cyberbullying among 6,260 students aged 11-23 from six European countries found that girls were victims more often while boys were perpetrators more often (Schultze-Krumbholz et al., 2015). Similar results can also be found in Canada (Li, 2006; Ronis and Slaunwhite, 2017), Sweden (Låftman et al, 2013), Israel (Heiman and Olenik-Shemesh, 2015), Belfast (Savoldi and Ferraz de Abreu, 2016) and Nigeria (Olumide et al., 2016). A study that examined over 5,300 students aged 11-15 in the United Kingdom (UK) found that girls were twice as likely as boys to report being cyberbullied (Public Health England, 2014, p.4). A study that examined cyberbullying among university students in Canada found that more female than male students experienced cyberbullying by a friend or acquaintance at the university and "female students were much more likely than males to report having experienced cyberbullying over social networks and via text messages" (Faucher et al., 2014). A large-scale study on cyberbullying among 31,148 teenagers found that cyberbullying victimization was more prevalent in females than males and female adolescents were more vulnerable to emotional and behavioural problems as a result of cyberbullying (Kim et al., 2018, p.669). In 2017, a survey conducted by Amnesty International revealed that about a quarter of 4,000 women surveyed across eight countries had experienced online abuse or harassment at least once and over 40 percent of them said that such experience threatened their physical safety (Amnesty International, 2017). The problem of cyberbullying against women and girls is a serious problem that deserves an in-depth investigation.

THE CAUSES OF CYBERBULLYING AGAINST WOMEN AND GIRLS

There are some reasons attributed to cyberbullying against women and girls. Female students are victims of cyberbullying because of their physical appearance, having different opinions or beliefs, upsetting other people, interpersonal problems (Faucher et al., 2014) and learning disabilities (Heiman and Olenik-Shemesh, 2015). They are also victims of cyberbullying due to relationship problems, including break-ups, envy, intolerance, and ganging up (Hoff and Mitchell, 2009, p.655). Break-ups that cause feeling of rejection lead to retaliation by ex-partner to publicly shame and humiliate the victim for ending a relationship (European Institute for Gender Equality, 2017; Hoff and Mitchell, 2009). Being envious of someone's achievements or popularity or being intolerant of someone's religion, disability and gender make the bully resort to online channels to vent anger and frustration (Hoff and Mitchell, 2009). Cyberbullying is "often due to ganging up on a person in order to reject and isolate that person from the 'group'" (Hoff and Mitchell, 2009, p.656). Cyberbullying can be seen as a continuum of bullying in the physical space. Female students who are victims of traditional bullying are also more likely to be victims of cyberbullying (Smith et al., 2008; Vandebosch and Van Cleemput, 2009).

It is common for females being targeted for cyberbullying due to their refusal to reciprocate the bully's romantic interest in them (D'Cruz & Noronha, 2013). Apart from being physically stalked by the bully, females are sexually harassed by the bully through emails (D'Cruz & Noronha, 2013, p.331). Their office computer systems, email and social media site accounts are hacked by the bully and their email identities are used by the bully to contact their family and friends (D'Cruz & Noronha, 2013). Cyberbullying can be committed by ex-partner or partners to seek interpersonal revenge or entertainment through distributing or sharing texts, non-consensual private or sexual images or videos of females online such as revenge porn-specific sites (Hall and Hearn, 2017). It is another form of gender violence and abuse representing a perception of regaining control and reaffirming a sense of masculinity (Hall and Hearn, 2017).

Workplace cyberbullying against women can come from their bosses, peers, subordinates or even former employees. This is due to the boss's "personality traits especially the needs to be in control and to get even in instances of perceived defiance" (D'Cruz & Noronha, 2013, p.332), peers being threatened by the female's competence, subordinates' grievance that were unable to share directly with their superiors, and former employees' revenge for being laid off from work (D'Cruz & Noronha, 2013). Low support from managers was related to higher exposure to cyberbullying behaviours for women non-managers while low support from colleagues was associated with exposure to cyberbullying behaviours for women managers (Forssell, 2018). Women also face online violence and abuse due to speaking out about some feminist issues, standing up to injustice and being public figures (Amnesty International, 2018, pp.14-8). Prominent women leaders, journalists, rights activists and bloggers are usually subjected to violence and abuse online, "especially when it is related to fields where men have been traditionally held as experts, such as gaming, politics and technology" (Amnesty International, 2018, p.15). In order to silence and exclude the voices of these women, the bully send violent and threatening messages such as death threats or rape threats to them online (Amnesty International, 2018). Cyber violence is used as a way of disciplining women for transgressions of traditional gender boundaries and force them into a subordinate position compared with men. Women also face violence and abuse online due to racial, religious, disability discrimination or discrimination based on sexual orientation or gender identity (Amnesty International, 2018).

THE CONSEQUENCES OF CYBERBULLYING AGAINST WOMEN AND GIRLS

3

Different studies show that cyberbullying against women and girls can lead to multifaceted consequences that negatively affect victims' self-esteem, physical and mental health, behaviours, relationship with other people and motivation to live, study and work. Female secondary school students who were victims of cyberbullying had lower body esteem that led to lower appearance and weight satisfaction (Olenik-Shemesh and Heiman, 2017). They had poorer subjective health, including headache, upset stomach, poor appetites, and sleep disturbances (Låftman et al., 2013). They had lower perceived peer acceptance, value of learning and importance of school (Betts et al., 2017). They had greater absenteeism and poorer grades in school. They felt helpless and lonely, had disillusionment and distrust of other people, social isolation and were reluctant to meet new people (Šléglová and Cerna, 2011). They showed signs of physical aggression targeted at other people (Šléglová and Cerna, 2011) and had more behavioral problems such as physical violence and conduct disorder (Kim et al., 2018). They had lower life satisfaction (You et al., 2016) but higher rates of emotional problems such as depression, suicidal behaviors (Reed et al., 2015) and substance use problems than their male counterparts (Elgar et al., 2014). Female college students who had experienced cyberbullying had almost three times the odds of meeting clinical criteria for depression compared to those with no cyberbullying experience (Selkie et al., 2015, p.82). They lost confidence and self-esteem, felt embarrassed, angry, frustrated and afflicted due to the lack of control with the situation (Brewer et al., 2012). University female students who had been cyberbullied reported that cyberbullying threatened their emotional security or physical safety, affected both physical health (headaches, stomach problems, nausea, heart palpitations or chest pain, sweating, etc.) and mental health (e.g. anxiety, depression, emotional outbursts, etc.) (Faucher et al., 2014). Cyberbullying also affected their ability to do assignments (e.g. productivity, loss of confidence, concentration problems, etc.) and obtain better grades, their personal relationships at the university and outside of the university and made them want to cyberbully back (Faucher et al., 2014).

Women that experienced cyberbullying at work had lower psychological health (i.e. depression, anxiety, and psychosomatic health) (Ford, 2013), higher mental strain, lower job satisfaction (Coyne, 2017) and lower task performance (D'Cruz & Noronha, 2013). They felt fatigued (Sansone and Sansone, 2015), scared and powerless, had physical and emotional distress, emotional exhaustion, headaches, blood pressure and gastrointestinal problems (D'Cruz & Noronha, 2013). Those who had experienced sexual harassment online suffered great trauma with poor physical and mental conditions (D'Cruz & Noronha, 2013). They were under great shock and stress and were unable to eat and sleep (D'Cruz & Noronha, 2013). They feared for their physical safety and worried about their personal and professional reputation (D'Cruz & Noronha, 2013, p.336). Cyberbullying can extend to the physical world when doxing can lead to stalking in the real world, undermining the physical safety of the victims and their family members. The survey conducted by Amnesty International revealed that cyberbullying had devastating psychological impact on female victims, with 63 percent of respondents having insomnia, 60 percent experiencing lower self-esteem or loss of self-confidence, 56 percent being unable to concentrate for long periods of time, 55 percent experiencing stress, anxiety or panic attacks and 24 percent feared for their family's safety (Amnesty International, 2017). The survey also showed that cyberbullying undermined female victims' freedom of expression, leading to victims refraining from expressing their opinions online, stepping back from public conversations or self-censoring out of fear for their safety or privacy (Amnesty International, 2017). Some may even choose to leave social media platforms to stop receiving abuse (Dhrodia, 2018, p.385).

SOLUTIONS AND RECOMMENDATIONS

Cyberbullying against women and girls is a form of violence that is just as damaging to women as physical violence (African Development Bank Group, 2016). It is also a form of discrimination that reinforces prejudice and a major impediment to achieving gender equality and the full advancement of women because of severely violating the principle of respect for human dignity and a range of women's rights, including the rights to life, equality, privacy, freedom of opinion and expression, and to be free from any physical, sexual or psychological violence. In fact, women deserve equal rights as men, which is enshrined in the International Covenant on Civil and Political Rights, the International Covenant on Economic, Social and Cultural Rights, and the Convention on the Elimination of Discrimination Against Women (CEDAW). Besides, "[r]ights of women in cyber space are as important as rights of women in physical space" (Halder and Jaishankar, 2012, p.55). It is important to identify and protect women's right in the cyber space so that women can be free from discrimination and violence. The adoption of a human rights based approach to combat cyberbullying against women and girls is to encourage rights holders to claim their rights as well as developing the capacity of duty-bearers to meet their obligations (United Nations Population Fund, 2014). Women being rights holders have the rights to privacy and freedom of expression online and to be free from any physical, sexual or psychological violence. Meanwhile, the adoption of a human rights based approach recognizes that duty bearers have the obligations to respect, protect and guarantee these rights (United Nations Population Fund, 2014). Being duty bearers, the government, private organizations and non-government organizations (NGOs) should formulate and implement policies to combat cyberbullying against women and girls.

Women have the right to safe and protected cyber life that allows them to be free from all sorts of gender abuses and harassments (Halder and Jaishankar, 2012, p.62), especially their rights to privacy and freedom of expression. It is necessary to provide women and girls with equal treatment for legal protection against cyber abuses and harassments (Halder and Jaishankar, 2012) so that they can obtain the justice they deserve. At present, most of the new laws or amended laws that are introduced to combat cyberbullying by countries are gender neutral in nature. For example, in the U.S., 48 out of 50 states have included cyberbullying or online harassment in their bullying laws while 44 states have criminal sanction for cyberbullying or electronic harassment (Cyberbullying Research Center, n.d.). Depending on the severity of cyberbullying, the perpetrator can face fines or imprisonment. Besides, 45 states have included school sanction for cyberbullying (Cyberbullying Research Center, n.d.). For example, Public Act 478 in Michigan requires schools to modify their anti-bullying policy to include cyberbullying as a form of bullying (State of Michigan, 2015) so that they have the duty to intervene on any reports of cyberbullying. The Criminal Code Act 1995 in Australia also addresses cyberbullying. In India, the Information Technology Act, 2000 deals with offences such as hacking with computer systems and breaches of confidentiality and privacy. Section 509 of the Indian Penal Code, which makes word, gesture or act intended to insult the modesty of a woman punishable, can be applied to address sexual abuse faced by women online (Padte, 2012). Many governments have yet to strengthen the legal system to protect women's rights against cyberbullying. As Article 2 of CEDAW states that state parties agree to "adopt appropriate legislative and other measures, including sanctions where appropriate, prohibiting all discrimination against women" (United Nations, n.d.), governments can consider drafting and introducing gender-centric law on cyberbullying based on the principles set forth in CEDAW.

Legislation alone is not enough to combat cyberbullying against women and girls. Other mechanisms should be provided by the government for victims and witnesses to report suspected cases of cyberbullying against women. For example, the Child Exploitation and Online Protection Centre (CEOP), which is

a command of National Crime Agency established in 2006 in the UK, allows the public to report cases of online sexual abuse and exploitation of children on its website. Up until September 2009, the CEOP had safeguard 515 children, arrested 821 suspected offenders, disrupted and dismantled 205 high risk sex offender networks (The Secretary of State for the Home Department, 2010, p.9). The Australian Cybercrime Online Reporting Network (ACORN) is a national online system that allows the public to securely report instances of cyberbullying and cybercrimes such as hacking and identity theft as well as providing advice for victims (Australian Cybercrime Online Reporting Network, n.d.). It does not have any investigative or recovery powers, but has been delivered in collaboration with all Australian police agencies, Attorney-General's Department, Criminal Intelligence Commission and so on (Australian Cybercrime Online Reporting Network, n.d.).

Another equally important issue is to provide sufficient training to law enforcement officers so that they can have the capacity to proactively prevent, prepare for and respond to cyberbullying incidents (Olsen, 2014). They should have a good understanding of laws related to cyberbullying (Olsen, 2014) and “maintain a working knowledge of the latest technology and social networking sites to successfully investigate cyberbullying cases” (Thaxter, 2010, p.530). They should work with the communities such as schools to develop clear procedures for determining if and how officers should respond to cyberbullying complaints (Olsen, 2014). They can form partnership with schools through a written memorandum of understanding to addresses the specific issue of cyber bullying, such as the issue of jurisdiction (Thaxter, 2010, p.530). They should know how to collect and document evidence of cyberbullying incidents, communicate with the victims and their family members, provide support to the victims, and increase public awareness of cyberbullying behaviors through education workshops (Olsen, 2014). For example, juvenile police officers in Massachusetts adopt a three-pronged strategy, namely education, intervention and adjudication, to handle cyberbullying incidents in schools (Thaxter, 2010, p.529).

Meanwhile, the government and NGOs should provide support services such as counselling service, referral service, mental health services and legal aids for women and girls subject to cyberbullying. For example, a UK-based charity Family Lives provides a confidential helpline for young people subject to cyberbullying to seek support and advice. Help123 in Singapore is a one-stop service for youth, family members and educators to get updated cyber wellness resources and appropriate support services from cyber wellness community agencies through hotline, email or webchat (Fei Yue Community Services and TOUCH Cyber Wellness, 2017). In Australia, the Office of the eSafety Commissioner provides channels for the public to report cyberbullying incidents, counselling services for those in need and online safety information and education resources for young people, parents, women and adults. Local Community Legal Centres in Australia allows those who are subject to cyber abuse to seek free legal advice (The Office of the eSafety Commissioner, n.d.). Besides, the government and NGOs should implement anti-cyberbullying campaigns to eliminate stereotypes about gender roles and sexual norms for women, raise public awareness of cyberbullying and empower the public with the know-how to prevent cyberbullying. For example, Better Internet Campaign was launched in Singapore to combat cyberbullying and raise awareness of cyberwellness issues through a series of outreach events in secondary schools and tertiary institutions (Hio, 2017 February 7). The campaign website contained personal stories and experiences of cyberbullying, which were told from the perspectives of bully and victim (Hio, 2017 February 7).

Some social media sites are criticized for their inconsistency and inaction on their own rules when women report violence and abuse (Amnesty International, 2018, p.33). They are criticized for taking action only when they are under pressure (Amnesty International, 2018, p.40) and “being considerably more responsive to reports which appear in the media, including those highlighted in newspaper exposés” (Home Affairs Committee, 2017, p.15). Providers of social media sites should perform due diligence

by developing effective policies that act against cyberbullying against women on their platforms. They should publish clear community guidelines to prohibit online violence and abuse against women. Besides, they have safeguarding responsibilities to proactively and quickly identify and remove abusive and discriminatory online content such as hate speech against women and unwanted sexual advances. They should lock or suspend the accounts of those who violate community guidelines and provide tools for women to protect themselves from cyberbullying by blocking cyberbullies, muting conversations and filtering out obscene contents or offensive remarks. They should provide a report link for users to report potentially breaching content and be more responsive to cyberbullying complaints. They should increase transparency by regularly publishing reports on their efforts to analyse and handle complaints of cyberbullying against women. They should “create appropriate record keeping systems specific to violence against women and classify and share the ways in which they have responded to it” (Amnesty International, 2018, p.45).

Employers have the responsibility to provide employees with a safe and healthy working environment free of cyberbullying behaviors. They should “adopt a clear policy, along with reporting channels and processes, to indicate to employees that the organisation takes cyberbullying seriously” (D’Souza, 2018). They should formulate policies that allow early intervention to de-escalate issues of cyberbullying and carry out disciplinary action for employees violation of workplace bullying policy. Besides, they should implement workplace bullying prevention program that also incorporates anti-cyberbullying practice. Preventive measures such as the introduction of web-filtering system and the provision of routine in-service training programs on respectful workplace interaction online should be implemented.

FUTURE RESEARCH DIRECTIONS

There is a pressing need to combat cyberbullying against women and girls at the national and international levels. However, actions taken to combat cyberbullying against women and girls are still inadequate. A human right based approach to combat cyberbullying against women and girls has not been strongly advocated in different countries. This may be due to the fact that stereotypes about gender roles and sexual norms for women are still deeply rooted in today’s society. Future research directions can examine whether the adoption a human right based approach can effectively combat cyberbullying against women and girls and examine best practices in combating cyberbullying against women and girls.

CONCLUSION

In conclusion, cyberbullying against women and girls is a major impediment to achieving gender equality and the full advancement of women. The adoption of a human rights based approach to combat cyberbullying against women and girls is to encourage women to claim their rights to privacy and freedom of expression online and to be free from any physical, sexual or psychological violence while recognizing the obligations of governments, employers, NGOs and social media site providers to respect, protect and guarantee these rights. Combatting cyberbullying against women and girls is an ongoing process that requires efforts to eliminate prejudice and the determination and commitment to create a culture of respect in the cyber space. Looking forward, it is anticipated that women and girls can enjoy the same rights as men when they are online.

KEY TERMS AND DEFINITIONS

Cyberbullying: The use of information and communications technologies (ICTs) by an individual or group to intentionally embarrass, taunt, harass, threaten, torment, or humiliate a person.

Depression: A mental disorder that causes a person to have constant feelings of sadness and worthlessness and lose interests in study, work, friends, hobbies and so on.

Freedom of Expression: The right of a person to freely express himself or herself orally or in writing.

Gender Equality: Equal rights and opportunities enjoyed by men and women.

Right to Privacy: The right of a person to be free from public scrutiny or intrusion into matters of a personal nature.

Stalking: To willfully trace, follow and monitor a person online without his or her consent.

Trolling: To disturb or harm another person by posting irrelevant, unpleasant, and offensive messages online.

Section 4

Cyber Security and Data Protection

Hexa-Dimension Metric, Ethical Matrix, and Cybersecurity

4

Wanbil William Lee

The Computer Ethics Society, Hong Kong & Wanbil and Associates, Hong Kong

INTRODUCTION

Enormous spending on protecting data continues, hacking continues, yet data protection must helplessly go on. This is attributable to a *vicious circle* born out of a technology-driven information-intensive *modus operati*, culminating in a *chronic problem* which is complicated by a *tripartite relationship* and exacerbated by a muddled view of the key concepts which hinders a wholesome appreciation of the problem. The consequence amounts to business opportunities for the data protection enterprises and employment opportunities for the information security practitioners but a nightmare that haunts corporate and information security managers and the netizens at large. Given the status quo, an ethics-based framework was perceived and developed with the aim to mitigate rather than eradicate, to lessen the incidence of hacking or make hacking exasperate. Grounded in Ethical Computing (Lee, 2015b), this ethical approach aims to identify the concerns of the stakeholders against the ethical values, and to evaluate and balance the issues thus identified and discovered which invariably involve conflicting interests. This Ethical Matrix and Hexa-dimension Metric (Lee, 2019) poise to lend a hand. This article is an exposition of the problem that leads to the new methodology and will end with an illustration of the newly adapted/developed tools.

BACKGROUND

Data Generation/Consumption/Protection – A Vicious Circle

Netizens can by means of the facilities provided by advanced interruptive technologies such as Big Data, Cloud Computing, IoT, AI and ML and so on conduct their daily activities more efficiently and effectively. These technologies enable integration of massive, scattered datasets, efficient interpretation of the integrated data, and speedier communication of the information. These facilities bring along obvious benefits and security threats on account of a huge amount of information being made available. As the cyber-world becomes a more transparent and open environment, netizens are better informed and able to innovate marketing, to accelerate business promotion, to enlarge data storage capacity and communication coverage, to increase retrieval facilities, and to improve transaction speed. At the same time, through that transparency loopholes in these new technologies where threats are bred provide opportunities for the cyber-miscreants to exploit and attack. However, as the clandestine activities that are brought to light, for example, the Snowden episode (*South China Morning Post*, 2013) and the Panama Papers leak (Wilson, 2016), the consequences can be beneficial to some people/organizations and adversary to others.

DOI: 10.4018/978-1-7998-3479-3.ch030

Figure 1. A conceptual graph of the circle and the phenomenon

The better-informed are the consumers, the more information is demanded and supplied. Supplying more information improves profit and uses more technologies. Using more technologies makes more information available. Consumers are happier and demand more information. More information is supplied and more technologies are used. The volume of information increases as more information is collected and generated. This culminates in a *vicious circle*.

Data Protection: A Chronic Problem

We spend more (the big spending on cybersecurity), we lose more (still get hacked and the enormous aftermath of the cyberwars) but data protection has to go on. The symptom is big spending and cyberwar and the cause is that we do not take ethics seriously.

The Big Spending: This the following exemplify: US\$1.5 billion by American financial institutions alone (US Homeland Security Research, 2016). £6.2m in 2016 compared to £3m in 2015 by UK organizations (CyLon, 2017). Gartner predicted in 2017 that worldwide spending to grow to \$93 billion in 2018 from \$86.4 billion in 2017 (Bradley, 2017), and forecasted in 2018 that Hong Kong's budget for data security (the fastest growing product category) would reach HK\$85 million in 2019, mainland China to reach almost 23.9 billion yuan (HK\$27.2 billion) and 27.3 billion yuan, respectively 2018 and 2019, and globally, expected spending on information security products and services to reach more than US\$114 billion in 2018 and to US\$124 billion in 2019 (Bushell-Embling, 2018).

Cyberwars symbolizes nation-to-nation conflicts such as the US-China trade-based and military-oriented cyberespionage (Onag, 2018), the alleged Russian interference of the US general election in 2016 (The New York Times, 2018a), and the UK allegation of Russia's tampering of Brexit voting (The New York Times, 2018b), also denotes conflicts at lower scales such as the fight between advertisers and users of ad blockers (Wicker and Karlsson, 2017) and the dispute between consumers of the digital technologies and

the cybermiscreants (Talevski, 2018). Cyber-ransom exemplifies another type of cyberwar, typified by the following three cases: WannaCry vs UK's National Health Service where dozens of computers were infected every minute and WannaMine vs the world, hijacking the computers around the world to mine a cryptocurrency called Monero (The Telegraph, 2017); and the case where the ransomware encrypted the files of infected users, and demanded for decryption US\$300 (HK\$2,300) in bitcoins within three days, US\$600 (HK\$4,700) after the three-day deadline, or all the files would be permanently encrypted after one week (in Hong Kong on 15 May 2017) (Hong Kong Free Press, 2017).

Why the futile result? Our first reaction would be to blame the data protection software. This is, however, not fair because the software is implemented according to the design so the fault should lie in the design, not the software. Then, the design itself should not be blamed because design is governed by the data protection policies (at corporate level) and security standards (at operation level). Therefore, the design which leads to unsatisfactory end-products is but a secondary cause at the next level. These policies and standards, by design, concentrate on ensuring a good return on investment of the technology (financial viability) and an optimal utilization of technologies acquired (technical efficiency) but are silent on the socio-ethical aspect of the problem. It follows that the software which is incapable of covering issues of a social/ethical nature is not to be blamed. The fault lies in the policies and standards. Does this mean that the primary cause is the policies and standards? Not quite; they are set by the decision-makers of the policies and standards who neglect the ethical elements in their deliberation and formulation. It follows that the ultimate cause is that we do not take ethics seriously.

Why don't we take ethics seriously? The problem is rooted in the way the data are collected about and are used adversely against data subjects and the *right* of the data subjects to that data, and has to deal the *techno-ethical-risk* which is originated in the way the technology is applied and the human users of the technology and the data, though the technology per se is neutral, yet the use of the technology is not (Parker, 1986; Neumann, 1995; and Williams, 1997). The protection of data privacy means to ensure that data privacy is not breached, that is, the data content is securely stored and accessed only with proper authority, and that the right of the data subjects not abused. Solving the problem means developing, reviewing, and implementing information protection and data privacy policies, standards, guidelines and processes (the policies), and mitigation measures; and to identify new technology risks; and to ensure that the policies are appropriately enhanced, communicated and complied with, and that mitigation measures are properly implemented. Also, our indifference to or lack of intrinsic interest in ethics, an attitude that most of us adopt, contributes to the primary cause. The muddled view of the basic concepts and the fallacious belief hinder a holistic understanding of and exacerbate our view. On many an occasion when ethics pops up in a conversation, many of us would say ethics is important but tend to obfuscate upon being pressed for elaboration. Not all of us, especially and more importantly the information technologists, have an intrinsic interest in ethics. The simple reason is our indifference to or lack of intrinsic interest in ethics, an attitude that most of us adopt. Muddled view and fallacious belief are the main culprits. A plain example is that on many an occasion when ethics pops up in a conversation among techies, the majority would say ethics is important but tend to obfuscate upon being pressed for elaboration. Not all of us, especially and more importantly the information technologists, have an intrinsic interest in ethics.

Security-Ethics-Law: A Tripartite Relationship

First, ethics and law are obviously closely related and mutually supportive of each other that the Donald Tsang case exemplifies. Law and ethics seem *separate* when the judge instructed the jury: "This is a legal

Figure 2. Ethics-Law-Security Chain (Source: Lee, 2015b)

Figure 3. Connecting Philosophy/Ethics and Technology/Security/Risk (Source: Lee, 2015b)

case, not a moral case” yet law and ethics are *linked* when the defence counsel pleaded for a suspended sentence and a shorter term premised on two points: “lack of morally questionable motive” and “heavier sentence if motives morally questionable” (*South China Morning Post*, 2017; Lau and Hollingsworth, 2017). Second, ethics and security are interlinked. In cyberspace as in the physical world, security relies on trust; trust depends on privacy; and privacy is breached if law is not observed and if ethical principles are not followed. So, one won’t trust, or disclose, anything confidential to any who does not respect privacy; one would trust his or her security to the protecting agent who would act according to ethical principles. Hence, trust will be lost or damaged and repercussions will come after if there is no privacy. No trust, no security: no one will trust you if you act in contradiction to ethics or fail to obey the rule of law, and absence of trust will block privacy for no one will disclose information of a private nature to an untrustworthy recipient. (See Figures 2 and 3 which depict the Ethics-Law-Security Chain (Lee, 2015b): abuse of the technology (by human-users) will lead to risk (techno-ethical risk) as it violates ethical principles – certainly a security concern.

Risk, Ethics, Privacy: In a Muddle

Many of us habitually or subconsciously take risk for physical damage, financial loss or punishment by law; ethics for some intangible concern about right or wrong, or good or bad; and think of privacy as the same as about being let alone or free from interference. These notions are not wrong but not enough for a wholesome appreciation of dilemmas or aftermath of cybersecurity cases. Risk, ethics, privacy and concepts related to them are in some kind of muddle and must be cleared, else the status quo will deteriorate, not improve.

Risk is more than is more than physical damages, financial losses, and criminal sanctions. Taking such a view largely attributes to the orthodox decision model by Simon (1976), or due to misinterpretation of risk. Risk has been treated as a technical entity and measured in economic terms only when it is in fact a managerial concern and should be evaluated in social as well as technical terms, and technical, economic and social aspects of risk should be recognized and given equal priority and evaluated holistically. A shift of view is imperative since a risk is in fact a managerial concern – as ethical risk and audit risk exemplify – it should be evaluated in social as well as technical terms. Taking home from work a USB containing corporate confidential data (a company asset) for personal convenience runs the risk of breaking company rules and breaching data privacy or confidentiality. In this case, obviously the technology (the USB) is used in contradiction to ethical principles, and a risk is formed when that threat exploits the vulnerability where taking home an USB is a Vulnerability, taking home an un-encrypted USB containing confidential data is a Threat. It is a new type of risk created when called techno-ethical risk, or simply ethical risk. A risk can be speculative if the outcome of ethical actions will bring about gains and unethical actions will yield a loss, or dynamic if the chance of occurrence is associated with technological change or change in general including man-made change. For example, security threats regarding privacy and culture of Cloud Computing are speculative because of the opportunity for potential revenue due to additional protection charges for guarding against invasion of privacy and for provision of resolving cultural differences; they are obviously dynamic, not static, as they occur not through irregular action nature flood, earth-quake, and so forth.

Ethics is more than about “right or wrong else there won’t be complaint that ethics is vague or slippery and there won’t be so many various principles/theories. Fallacy plays a significant role: ‘What is legal is ethical’ is a fallacious. To distribute mailing lists without permission is legal but unethical for it is not explicitly prohibited by law but may step over the privacy of the people on the lists; to copy pro-

proprietary software as a backup, even when the agreement specifically prohibits copying for any purpose is ethical but illegal because it may be tolerable but may infringe the copyright law. ‘If you can do it, so can I’ is often heard but supposing ‘what you do’ is wrong, then I do wrong, too! This is a circular or relative argument that tell ‘what you do’ is right or wrong as ethical theories such as Relativism and the Golden Rule give no indication of an action being ‘right or wrong’. Hence, there is need for other theories such as those based on ‘duty’ and ‘results of action’. Further, ethics has an Invisible-Hand with a dual function with a double-edged sword effect. Diagnosing an action, ethics plays the role of an attacker by exposing unethical consequences if that action violates ethical principles and of a defender if the action is consistent with the ethical principles.

Privacy is not the same as being alone. For example, two people can have a private relationship that might be physical or intellectual. Stepping over the line of someone’s privacy is rude and ethically unacceptable but it affronts that person’s dignity, not that person’s privacy. However, it is a violation of someone’s privacy when that someone is treated as a means to an end. Privacy can, in simple terms, be viewed as a “zone of inaccessibility” or “right to be left alone”. The former defines the extent to which one can control who has access, meaning that one has privacy in this zone, and entering this zone without permission is a violation of privacy, and is prohibited; the latter may mean that privacy can be “being let alone” or “being free from intrusion” or “physically being let alone” or “being free from intrusion into one’s physical proximity”.

In a digital business context, data privacy or cyber-privacy relates closely to cybersecurity. Data privacy is a legal cum ethical issue that concentrates on data governance and data use; so it defines the organization’s rules and procedures for collecting, storing and using personally identifiable information (commonly abbreviated as PII) in a rightful way. Cyber-privacy (a particularly instance of cybersecurity) is a managerial, operational issue that focuses on security and demands certain actions to protect data; it takes actions according to those rules and procedures to protect data against unauthorized access, corruption and loss using encryption, secure communications protocols and measurable security policies. So, data privacy and data protection are certainly similar and often overlap but not always synonymous but not always equal, especially in the digital business context because it is extremely difficult to ensure privacy when data are not protected by technology. If someone can maliciously use an individual’s personal information, its privacy is wholly uncertain. It is important that organizations that act as the data processor and controller employ data protection technologies to fortify the governance processes of the data. To this end, many organizations consider taking data privacy audit (check and ensure data governance and classification, data security, and third-party contracts). Notwithstanding, data privacy should not only consider merely data protection but also contractual principles because when using Google, Baidu, Amazon, Alibaba, Facebook and others, we all agree with these companies’ terms and conditions. Data protection is a technical and economic thing (the cost of data privacy breaching for example) and requires technical actions to uphold accuracy, completeness, availability, etc of the data content, and to admit only authorized access, and so on. Contractual principle is a legal thing and must observe the laws of the land. This techno-legal definition tells us that data privacy is achieved when technical efficiency and economic/financial viability are met.

Given that ethics varies depending on culture, time and geography, so does privacy. This raises a string of questions about value. Privacy does not have a stable universal value, but it has an intrinsic, a core and a social value (which is regarded as commonly applicable universally to cases perceived to have these values); the techno-legal definition is deficient, thus data privacy should also consider social acceptability to cover cases where value depends local law in force, culture or habit in fashion at the time being, in addition to technical efficiency and legal viability.

RECOMMENDED SOLUTION

The proposed remedy is ethics-based, aiming at mitigation rather than eradication and comprising the following:

- Take ethics seriously
- Have a sound understanding of the applicable theories of ethics and be adept to linking actions to these theories
- Adapt to a shift of view of risk and ethics
- Carry out ethical analysis and be adept to applying the *Ethical Computing* tools that include *Ethical Matrix* and *Hexa-dimension Metric*

Ethical Computing Feasibility

The ethics-based remedy feasible on account of

- Keeping all hackers out is unrealistic or impossible.
- Any aftermath of cyberattacks that the like of Cambridge Analytica exemplifies cuts through all three domains of law, ethics and security.
- Ethical Computing, a practice grounded in Computer Ethics, is poised to supply the ethical doctrines (to persuade against wrong-doings) and to take ethical actions (to nurture trust) with the resultant effect to relax or soften the demand on data protection and gradually reduce the information security budget and the cost of cyberattacks
- The attitude that ‘*we don’t take ethics seriously*’ is automatically taken care of. The IT community generally recognizes that ethical issues exist, and considers them important. Reflective of this point and attesting recognition at national level of the importance of ethical issues is the establishment of the Data Ethics Council in June 2016 by the UK government “as a means of addressing the growing legal and ethical challenges associated with balancing privacy, anonymization, security and public benefit” due to the problem caused by Big Data. Another sign that ethical issues are getting the attention they deserve at international level is that EU enforced a more stringent data protection standard through its GDPR (in force from 25 May 2018).
- *The knowledge of ethics has the effect of guiding us to ethical use of the computer.* A seven-year exploratory study supports this hypothesis. The resulting statistics (Table 1) indicate that 8% of the students (including those matured age part-timers with over ten years professional experience) claimed that they were aware of Computer Ethics but not certain if they use the computer ethically at the start of the course, compared with 72% claimed that they understood ethics and would use the computer ethically at the end of the course, and the remaining 28% (post course population) claimed no change for various reasons. Overall, knowledge of ethics has a remarkable impact. It is noteworthy, however, ethics has no impact on 21% (post course population) who claimed that understanding ethics did not change how they use of the computer. The empirical data is consistent over the seven consecutive years ($p > .05$). (Lee & Chan, 2008)

Ethical Computing

Ethical Computing is the practice of *Computer Ethics* that identifies/discovered ethical issues arising from developing and using computer-based application systems, and analyzes these issues to come up with balanced solutions. Its current major issues of interest include privacy, intellectual property, digital-divide, professionalism, trust, anonymity, cyberbullying and netiquette. Its methods and tools for ethical analysis include the *Ethical Matrix* and *Hexa-dimension Metric* among others (Lee, 2015a; Lee, 2019)

Computer Ethics

Ethics is same in peace times as during the *cyberwar era*. *Computer Ethics* or cyberethics, is a relatively new Applied Ethics. Defined slightly differently in the literature, notably Moor (1985) and Johnson (2009), the field is basically concerned with the *ethical issues* surrounding the computer. In this paper, Computer Ethics is viewed as a dual mission and a dual function (Figure 4) (Lee, 2014-15).

Figure 4. Conceptual Graph – Double Duality (Source: Lee, 2014-2015)

Ethical Matrix

This is a tool originally developed for the food and agriculture industry to carry out ethical analysis. The rows represent the stakeholders (relevant to the issue being studied); the columns correspond to the *prima facie* ethical principles respected for; and the cells contain the concerns (the main criterion that would be met if the specified ethical principle were respected for a particular stakeholder). The matrix is based on *prima facie* principles or rules of action that are valid at first sight. The advantage is that these principles allow a stronger case to overrule a weaker case in particular circumstances, thus facilitating ethical decision-making (because following the rules rigidly might lead to a deadlock or endorsing conflicting courses of action). (Mepham, etal, 2006, pp 8, 9)

Adapted for ethical analysis in the IT context, the columns of the matrix correspond to *values* held by stakeholders with respect to ethical principles, and the rows correspond to the stakeholders or inter-

est groups. The number of columns and rows varies as required. The cells contain the concerns of the stakeholders (the main criterion that should be met) with respect to the value held (by the stakeholders) or a particular ethical principle. (Lee, 2015a)

Hexa-Dimension Metric

This is developed as an aid to decision making in an IT context, aiming to supplement the variates that the orthodox decision model did not cater for and, as a checklist to ensure that the important aspects (six) are taken into consideration in the decision process. The six principles/measures are

- financial viability – to justify return on the investment on technology, that is, ensure that the actions taken are financially sound and viable consistent with the corporation's performance metric on operational goal, risk absorption standards and limits, etc. as advised by the Finance and Operations experts, and measured by ROI and NPV.
- technical effectiveness – to ensure of utilization the technologies is optimized, that is, use of up-to-date technology to meet targets effectively and efficiently
- legal validity – to ensure that the laws current in force and the organization's rules and conventions are abided at the advice of the corporate counsel or the Legal Department, and is measured by the extent and degree the law is obeyed
- ethical acceptance – to take actions that are consistent with ethical principles and the corporation's Public Relations and Human Resource Management policies using the Ethical Matrix method (Lee, 2015b) to assess the consistency with the relevant ethical principles of duty and reciprocity.
- social acceptability – to make sure that the benefit of all stakeholders including the public has been considered and deliberated consistent with local culture and habit and can be measured by survey results of the extent of public benefited based on the ethical principles of utility and consequence, and that the huge amount of data consumed and generated by the technology is safe and not abused
- ecological sustainability – to protect the environment since running the technologies consumes a lot of natural resources including electricity, water, paper, etc., and generates air, noise pollution and to take actions that are friendly (not harmful) to the environment aligned with the policies of energy/materials saving, noise and air pollution control, radiation emission rate and so on using, for example, EIA (environmental impact assessment) laid down by the Hong Kong Government

Incidentally, the GCF Computing (Patrignani & Whitehouse, 2014) correspondingly and independently cater for the six measures. Namely,

- **Good Computing** which targets at workable & technically efficient deliverables and applies the internet technologies, Big Data, Cloud Computing, Ubiquitous computing (Evasive Computing), etc, handles Legal, Technical & Financial efficiencies.
- **Clean Computing** which aims at energy & materials savings and applies Green Computing (environmentally responsible and eco-friendly use of computers and their resources – Technopedia), handles Environmental efficiency
- **Fair Computing** which is concerned with corporate social responsibility and applies Ethical Computing (Lee, 2015b), handles social and ethical efficiencies

Operationalizing

- Initialize the remedial procedure requires a 5-item precondition:
 - Board of Directors support with respect to corporate policy aspects
 - cooperation of the supporting infrastructures including the organization's human resources management, legal, finance, and ICT functional units with respect to technical support and reference
 - the inclusion of a mandatory appraisal of ethical consistency in conduct in an annual performance review
 - identify the relevant critical factors depending on the target end-users (corporate-wide or a functional unit, nature of operation – for example, environmental impact is critical for a mining company or a factory, but may probably be skipped for an Information Security Unit)
 - determine a scheme for quantifying the elements of each factor for measuring, prioritizing and balancing the factors. Depending on the attributes/factors determined, the steps to be taken to measure the effectiveness culminates in an operationalization scheme (Table 1)

Table 1. Schedule of operationalization

Generic				User specific	
Attributes/factors	Remarks	Control	Targets	Drivers (*)	Supported by
Legal validity	Abiding the law, rule & regulations currently in force	External	Local law and convention	Corporate counsel /legal dept.	Good Computing
Social desirability	Beneficial to all stakeholders including the general public	External	Local culture and habit; standards for perceivable benefits to primary stakeholders and the public		Fair Computing
Ecological sustainability	Friendly to natural and industrial/business environment	External	Policy/guidelines for energy/ materials saving; ecology related law (if any)		Clean Computing
Ethical acceptability	Consistent with ethical principles	Internal	Corporate social responsibility; corporate culture	PR, HRM	Fair Computing
Technical effectiveness	Use up-to-date technology to meet targets effectively and efficiently	Internal	Sufficient & necessary human & technological resources to support infrastructural support	ICT, HRM	Good Computing
Financial viability	financially sound and viable	Internal	Corporate policy (performance metrics: operational goal, risk absorption standards & limits, etc.)	Finance, Operations	Good Computing

ILLUSTRATION

The Octopus Case: Selling Customers' Personal Data

The Story

The Company sold cardholders' personal data and milked HK\$44 million+; the Privacy Commission investigated and prosecuted; some legislators demanded a legal investigation; and the CEO eventually resigned. (South China Morning Post. 2010). The CEO insisted that

- “She didn’t do anything wrong (nothing illegal)”.
- “Everybody is doing it”.
- “She had a duty to run a profitable operation”.
- “The money from sales has gone to the company profit, a positive return to shareholders”.

Ethical Analysis

So, she did nothing illegal. But is her action ethical? She made a circular argument relying on *Relativism* which is akin to saying “If Joe dumps his rubbish next door in Sue’s backyard, why can’t I do the same to Jenny, else I won’t be as smart as Joe if I don’t do that”.

So, she got a duty to perform, to make a profit for the company and the shareholders – a *deontological* (duties-based) argument. She had done her job well; the result was beneficial to the company and shareholders – a consequentialist (results-based) argument. The consequence may be good, but for whom, for how many people – herself only, the company and shareholders, the majority of the whole population of Hong Kong?

The proceeds from selling the data benefits the CEO and perhaps the company and shareholders, certainly not the cardholders, not to mention to rest of the population. This is certainly not consistent with the *utilitarian doctrine*. The cardholders have been cheated and treated as a means to the CEO’s want. This contradicts the *categorical imperative*. The CEO acted against the *Gold Rule* as she certainly won’t like to see her own personal data being collected by a third party without her knowledge and permission, and sold for a profit.

Lastly, collecting cardholders’ personal data inconsistent with the purpose and selling them without the data subjects’ consent defy the value cherished and cared by the majority of people – an action against *virtue ethics*.

Ethical Matrix Analysis

Table 2 displays the stakeholders identified, the ethical principles respected for, and the stakeholders’ concerns. The matrix reveals that

- The CEO’s main concern is obviously her job security, undoubtedly a duty for herself. Finding a way to improve or bring in a profit is natural and fine. However, that way must be consistent with the ethical principles. She fulfilled her duty; she did nothing illegally; she may or may have a clear conscience with respect to selling the cardholders’ personal data; she may not be looked at approvingly by the Golden Rule but she certainly deviated from the Categorical Imperative.

- Those cardholders who signed up for the Octopus Rewards were obviously attracted by the benefits that they were most interested in. This raises the issues responsibility and rights: Shouldn't they bear certain responsibility? Were they in a position to complain of being cheated?
- And more.

Table 2. Ethical Matrix - a First-cut Result

Values Stakeholders	Well-being (utilitarian/consequential)	Deontic Ethics	Virtue Ethics	Justice/Fairness	Golden rule	Categorical imperative
CEO	Job security	Performance as CEO	A clear conscience	Not stepping over the redline	Self-protection	Not appear to taking advantage of others
Cardholders	Enjoyment of benefits provided by the scheme	Materialize the benefits promised	Confidentiality of personal data	Fair, prima facie	Self-interest	Ensuring not to be exploited
The Company & shareholders	Profit & ROI	Performance monitoring	Company image and reputation	Meeting the set profit margin		
Regulators	Fair and just way trading	Proof of fair trading		Compliance of fair & proper trading		

Hexa-Dimension Metric

Table 3 shows that the problem does not involve technology or use of technology even though the use of the card is an application of information technology. Hence the technical and ecology measures are excluded from the analysis. However, as indicated, the ethical and social dimensions of the action (i.e., collecting and then selling personal data) must be addressed.

Further work to quantify the stakeholders' concern (expressed in the cells of the Matrix) and the verdicts, called indicators, remained undone and will be continued in future. The indicators will enable the users to prioritize the issues and the allocation of resource to rectify the deficient areas.

Table 3. Hexa-dimension Metric

The measures	Verdicts	Check
Financial viability	Making that extra income is financially viable for the CEO, the Company and shareholders but at the expense of the Octopus Rewards participants	Ö
Technical effectiveness	Not a technical issue; not applicable	n. a.
Legal validity	No prima facie evidence of illegal action	Ö
Ethical acceptability	Data collection and data use ethically questionable; unacceptable	×
Social desirability	Questionable in utilitarian view	×
Ecological sustainability	Not an ecology issue; air pollution or climate are non-issue; obviously not applicable	n. a.

FUTURE RESEARCH DIRECTIONS

The concept that a decision should meet the six criteria is new, but each criterion in the hexa-dimension metric model is not new. The metric has the potential to serve others purposes, for example, Management Science: the metric can be used for enhancing identification and evaluation of the relevant factors of the traditional and popularly adopted decision model like the rationality and logic based Simon model (1976). Such decision models are no longer sufficient because decision makers are not always rational and sometimes non-rational, or judgmental decision making based procedural or bounded rationality (Gigerenzer, 2001) and escalation of commitment decision making that “under certain conditions, decision makers who make an initial decision become overly committed to the original choice and then subsequently make decisions biased by psychological commitment” (McCarthy, Schoorman and Cooper (1993, p. 9)). Also, that the decision variables are formulated and measured mainly in economic terms must be updated as they are also legal, ethical, social, and more recently, ecological in nature. This raises several questions for future work:

- Quantify the results provided by the Matrix and the Metric – developing a method for evaluating
- Field-test the efficiency of Hexa-dimension Metric for designing a code of practice in an IT organization using a prototype. On-site study of its effectiveness as a handy reference at the different levels of the corporation (Lee, 2019)
- An empirical study of the Metric to enhance the chance and scope of finding factors likely to bring about ethical, social and ecological repercussion on decision making

CONCLUSION

The information security professionals are in urgent need of effective and pragmatic guidance as the information security function in a technology-driven information-intensive environment becomes more complicated and harder due to the new socio-techno risks. Data privacy protection becomes a primary concern as privacy breach occurs more frequently and leads to devastating consequences to the individuals, corporations and governments. The newly developed framework, though at this embryonic stage of growth still awaiting empirical evidence and popular acceptance in the IT arena, poises to play a useful role, to release the burden on as the extant policies and standards including the privacy laws such as UK’s DPA (UK Government, 2018), EU’s GDPR (GDPR, 2019), and Hong Kong’s PDPO (Office of the Privacy Commissioner for Personal Data, Hong Kong, 2019).

To operationalize the ethics-based mitigation requires the Board’s mandate and inter-departmental support, identification of the relevant critical factors depending on the target end-users, a scheme for quantifying the elements of each factor for measuring, prioritizing and balancing the factors. As illustrated, Ethical Matrix is useful in providing a holistic view of the stakeholders and the issues of concern with respect to principles they value, and Hexa-dimension Metric in checking an action against the six measures, hopefully to reach a more complete and balanced conclusion.

It is worthy of note that the Hexa-dimension Metric is an initiative prompted by the phenomenon that no matters how meticulous is the decision-making process, the results are seldom satisfactory. Why such a phenomenon appears at all is akin to “man doesn’t live on bread alone” or decisions that are argued in rational, logical and financial terms only, and is reflective of the Simon Model, the guiding light for decision making which is deep-rooted in our thought and practice of management, being congenitally

defective. The fault lies in some kind of self-contradiction for the Simon doctrine assumes that decision making is rational and objective and the decision variables are considered in financial terms only yet the fact is that decision makers are not always rational and sometimes judgmental or reliant on escalation of commitment, or emotional, and risk and cost can be ethical, social, legal, technical and ecological in nature. A shift of view of risk and cost is advisable.

Referring to the chronic problem where hefty investment in the expensive technologies, it is a matter of course to expect a justifiable return, and an optimized rate of utilization of the expensive technologies. To measure success at this point in financial and technical terms is essential. Since the huge amount of information generated can be abused, both legal and ethical issues arise. The use of the information may serve well some, but not some other, stakeholders, so immediately emerged are social issues. As more technologies are used, thus more natural resources consumed, impact on the environment must be considered. In sum, to arrive at a satisfactory solution, decision makers must consider financial viability, technical effectiveness, legal validity, ethical acceptance, social desirability and ecological sustainability. To balance or strike a trade-off among the six attributes and measure the outcome thereof, the Hexa-dimension Metric is recommended. Hence, the Hexa-dimension Metric is a good instrument not just for privacy protection policy formulation but also for clarifying/determining pragmatically “ethical” and “effective” in ethical leadership and effective leadership which all professionals would strive for.

KEY TERMS AND DEFINITIONS

Chronic Problem: Refers to the situation that we spend more (the big spending on cybersecurity), we lose more (still get hacked and the enormous aftermath of the cyberwars) but data protection has to go on.

Ethical Analysis: Is about considering the competing factors when making ethical decisions because, at any one time, our behaviour may be affected by these factors which may be physiological, legal and spiritual. In common practice are three approaches: legal, formal or informal guidelines, and four principles: harm minimization, deontological (rights and duties) and consequentialist (outcome of the action) principles and Kantian categorical imperative (consistency and respect). Tools and methodologies in use typically linear menu-driven list consisting of four or five steps. Ethical Matrix was introduced but not yet popular until lately (see the next item). In any case, the aim of analysis is to identify the stakeholders and the concerns arising as a consequence of an action with respect to some ethical principles that the stakeholders value.

Ethical Matrix: Is a tool for ethical analysis adapted from Food and Agriculture to the IT context. The columns of the matrix correspond to *values* held by stakeholders with respect to ethical principles, and the rows correspond to the stakeholders or interest groups. The number of columns and rows varies as required. The cells contain the concerns of the stakeholders (the main criterion that should be met) with respect to the value held (by the stakeholders) or a particular ethical principle.

Ethics: Is simply put about right and wrong. But it is more than that. Deontic ethics is about duty-based actions taken according to principles of duty and rights; utilitarian ethics is on result-based action taken consistent with the consequence and utility doctrines. Judging an action being ethical may refer the gold rule, categorical imperative, virtue ethics, etc.

Ethics-Based Remedy: Aims at mitigation rather than eradication and comprises the following: take ethics seriously, have a sound understanding of the applicable theories of ethics and be adept to linking actions to these theories, adapt to a shift of view of risk and ethics, carry out ethical analysis and be adept to applying the ethical computing tools that include ethical matrix and hexa-dimension metric.

Hexa-Dimension Metric: Is a checklist to ensure that the important aspects (six) are taken into consideration in the decision process. The six principles/measures are financial viability, technical effectiveness, legal validity, ethical acceptance, social acceptability, and ecological sustainability.

Privacy: Is not the same as being alone; it is about one's "zone of inaccessibility" or "right to be left alone". Intruding into that zone is a violation of privacy and ignoring that right is an act of bullying, both are subject criminal charges.

Risk: Is more than is more than physical damages, financial losses, and criminal sanctions. Using the technologies in contradiction to ethical principles is a techno-ethical risk or ethical risk. There are also speculative risk (if the outcome of ethical actions will bring about gains and unethical actions will yield a loss), dynamic risk (if the chance of occurrence is associated with technological change or change in general including man-made change).

Tripartite Link: Symbolizes the interrelationship among Ethics, Law and Security where security relies on trust; trust depends on privacy; and privacy is breached if law is not observed and if ethical principles are not followed.

Vicious Circle: Depicts the phenomenon: The better-informed are the consumers, the more information is demanded and supplied. Supplying more information improves profit and uses more technologies. Using more technologies makes more information available. Consumers are happier and demand more information. More information is supplied and more technologies are used. The volume of information increases as more information is collected and generated.

A Utility Theory of Privacy and Information Sharing

Julia Puaschunder

The New School, USA

INTRODUCTION

Utility theory is concerned with people's choices and decisions based on preferences and values (Fishburn, 1968). Representing satisfaction experienced, utility is derived from the self-attributed worth and goodness of an option compared to other options. Standard neo-classical economic theory describes utility as a set of internally-consistent assumptions about options in the wish to maximize utility (Fishburn, 1968). Utility theory has leveraged as one of the most dominant theories in economics as an underpinning of rational choice and game theory. Utility is usually revealed in people's willingness to pay different money amounts for different options, leading to the concept of revealed preferences (Samuelson, 1937).

Whereas economic utility studies primarily focus on prescriptive approaches to guide how people should behave to maximize their well-being (Arrow, 1951, 1958; Majumdar, 1958; Simon, 1959); decision sciences started capturing how people actually decide regarding choices in an uncertain world and over time (Becker & McClintock, 1967; Edwards, 1954, 1961; Luce & Suppes, 1965). Expected utility theory introduces a first temporal discussion of expectations of utility rather than the actual utility derived from a choice (Alchian, 1953; Marschak, 1950; Strotz, 1953). Von Neumann and Morgenstern (1953) introduced that outcomes of choices are not known with certainty but have probabilities of occurrence, which weighted linear combination allows inferences about the overall utility derived over time.

Since the end of the 1970ies, a wide range of psychological, economic and sociological laboratory and field experiments proved human beings deviating from rational choices as standard neo-classical profit maximization axioms to fail to explain how human actually behave (Kahneman & Thaler, 1991). Human beings were shown to use heuristics in the day-to-day decision making as mental short cuts that enable to cope with information overload in a complex world (Bazerman & Tenbrunsel, 2011; Kahneman & Tversky, 1979; Thaler & Sunstein, 2008).

As one of the most recent developments in utility theory studies, behavioral economics find human utility choices biased (Bowles, 2004; Camerer, Loewenstein & Rabin, 2004; Ebert & Prelec, 2007; Kahneman, 2011; Okada & Hoch, 2004; Putnam, 2002; Sen, 1971, 1993, 1995, 1997, 2002a; Zauberman, Kim, Malkoc & Bettman, 2009) by heuristics (Kahneman, Slovic & Tversky, 1982; Simon, 1979), analogical thinking (Colinsky, 1996; Gentner, 2002), and minimized effort (Allport, 1979; Shah & O'penheimer, 2008).

In particular, people's cognitive capacities to consider future outcomes in today's decisions are limited (Doyle, 2013; Laibson, 1997; Loewenstein, 1992; Milkman, Rogers & Bazerman, 2009; Read, Loewenstein & Kalyanaraman, 1999; Read & van Leeuwen, 1998). Laibson's (1997) hyperbolically decreasing discounting functions more accurately describe choice behaviors of individuals, who tend to be impatient for smaller rewards now rather than waiting for larger ones later (e.g., Ainslie, 1992; Becker & Murphy, 1988; Doyle, 2013; Estle, Green, Myerson & Holt, 2007; Frederick, Loewenstein & O'Donoghue, 2002; Green, Fry & Myerson, 1994; Green & Myerson, 2004; Hansen, 2006; Henderson & Bateman, 1995;

DOI: 10.4018/978-1-7998-3479-3.ch031

Kirby, 1997; Kirby & Marakovic, 1995; Laibson, 1997; Loewenstein & Prelec, 1993; Mazur, 1987; Meyer, 2013; Murphy, Vuchinich & Simpson, 2001; Myerson & Green, 1995; Rachlin, Raineri & Cross, 1991; Sterner, 1994). Dynamically inconsistent preferences reverse as people are patient when deciding for the future and impatient when choosing for now (Hornsby, 2007; Laibson, 1997; McClure, Ericson, Laibson, Loewenstein & Cohen, 2007; Meyer, 2013; Reed & Martens, 2011; Thaler, 1981).

Field and laboratory experiments provide widespread empirical evidence for hyperbolic discounting and self-control failures (Frederick et al., 2002; Hoch & Loewenstein, 1991; Sen, 1971, 2002b) on money management (Alberini & Chiabai, 2007; Chabris, Laibson & Schuldt, 2008; Collier & Williams, 1999; Harrison, Lau & Williams, 2002; Keller & Strazzer, 2002; Kirby & Marakovic, 1995; Laibson, 1997; Laibson, Repetto & Tobacman, 2003; Salanié & Treich, 2005; Slonim, Carlson & Bettinger, 2007; Thaler & Shefrin, 1981; Warner & Pleeter, 2007), financial benefits (Cairns & van der Pol, 2008), credit card debt (Meier & Sprenger, 2010; Shui & Ausubel, 2004), medical adherence (Trope & Fishbach, 2000), public health (Bosworth, Cameron & DeShazo, 2006; Cameron & Gerdes, 2003; Chapman, 1996; Duflo, Banerjee, Glennerster & Kothari, 2010; Horowitz & Carson, 1990; van der Pol & Cairns, 2001), addiction (Badger, Bickel, Giordano, Jacobs, Loewenstein & Marsch, 2007; Becker & Murphy, 1988; Heyman, 1996; Laux & Peck, 2007; Madden, Bickel & Jacobs, 1999; Petry & Casarella, 1999), social security (Mastrobuoni & Weinberg, 2009), fiscal policies (Keeler & Cretin, 1983), commitment (Duflo, Kremer & Robinson, 2008; Sen, 1977, 2002b), health exercise (DellaVigna & Malmendier, 2004, 2006), employment (DellaVigna & Paserman, 2005), procrastination (Reuben, Sapienza & Zingales, 2010), diet (Read & van Leeuwen, 1998), subscription discipline (Oster & Scott-Morton, 2005), animal care (Green et al., 1994; Mazur, 1987), and consumption (Milkman, Rogers & Bazerman, 2008; Read et al., 1999; Wertenbroch, 1998). Failures to disciplinedly stick to plans for giving in to immediate desires (Ainslie & Haslam, 1992; Read, Frederick & Airoldi, 2012; Strotz, 1956) are explained by people caring less about future outcomes in the eye of future uncertainty (Luce & Raiffa, 1957; Shackle, 1955), perceived risk (Mas-Colell, Whinston & Green, 1995), and transaction costs (Chung & Herrnstein, 1967; Epper, Fehr-Duda & Bruhin, 2011; Frederick et al., 2002; Kirby & Herrnstein, 1995; Mazur, 1987; Read, 2001). Presenting temporal snapshots for now and later concurrently helps overcome myopia and decision-making fallibility (Puauschunder & Schwarz, 2012). In all these studies missing is an investigation of human decision making on preferences for information sharing and privacy.

Although communication and non-communication are day-to-day decisions of individuals; to this day, there is no stringently tested utility theory of information sharing and privacy. We lack a coherent decision science framework about when people choose to share information and when they rather want to stay silent for the sake of privacy. From the economic perspective, information sharing may impose temporal irreversible lock-ins or tipping points. The point of information sharing may be a reference point, in which one bit of more communication gives less utility than one bit of less information shared, hence one bit of more privacy, grants more utility in the sense of Kahneman & Tversky's (1979) behavioral decision science finding 'losses loom larger than gains.' There may also be a marginal decreasing utility derived from one bit more information shared but an exponential marginal utility gain from one more unit of information received given the fact that information can be put into context and an exponentially increasing marginal utility of information. Education, for instance, is the only good with an exponential marginal utility increase, as the more information one holds, the more complex connections one can make and use.

In the past, communication was depicted to decentralize organizations (Crémer, Garicano & Prat, 2007). Media was initially promoted to offer means of information transfer, political participation and protection against political abuse (Delli Carpini & Keeter, 1989; Neuman, Just & Crigler, 1992; Norris

& Sanders, 2003; Prat & Strömberg, 2005; Snyder & Strömberg, 2010). Evidence suggests that media coverage increases voter information, which increases the responsiveness of votes to policy, which increases the effort and selection of politicians, thus producing better policies (Prat & Strömberg, 2013). Media thus traditionally was portrayed as helping to keep politicians accountable (Prat & Strömberg, 2013). Media coverage was found to improve selection and incentives of politicians alongside voting responsiveness (Iyengar & Kinder, 1987; Snyder & Strömberg, 2010).

Critical studies in this regard show that there are negative downsides of transparency (Prat, 2005). Mass media can also erode social capital, as they potentially isolate people from real-world experiences (Olken, 2009; Putnam, 2000). A positive relation between federal funds per capita allocation to areas where the media covered political parties in power was found (Snyder & Strömberg, 2010). Research has been done on the effect of conventional media on politics including a nomenclature of biases that impose problems – especially against minority opinions (Prat & Strömberg, 2013). Ideological biases are found in conventional media and media effects captured on vote choice (Prat & Strömberg, 2013). While the negative facets of information on elections and the role of social media on voting outcomes has been widely discussed recently; yet to this day no stringent theoretical or empirical framework for the utility of privacy and information sharing on social media exists.

In the digital age, to study the trade-off between information sharing and privacy has leveraged into unprecedented importance. Social media revolutionized human communication around the globe. As never before in the history of humankind, information about individuals can be stored and put in context over time and logically placed within society thanks to unprecedented data conservation and computational powers. The big data era, however, also opened gates to unprecedentedly reap benefits from information sharing and big data generation (Puaschunder, 2017). The so-called nudigital society was recently introduced, shedding light onto the undescribed hidden social class division between social media users and social media providers, who can benefit from the information shared by social media users. Social media users share private information in their wish to interact with friends and communicate to public. The social media big data holder can then reap surplus value from the information shared by selling it to marketers, who can draw inferences about consumer choices. The big data can also be used for governance control purposes, for instance border protection and tax compliance control.

Drawing from the economic foundations of utility theory, this paper seeks to introduce the first application of utility theory to a preference-values predicament between communication and privacy in the new media era. Behavioral economics insights are advanced in shedding novel light on the conflict between the humane wish to communicate now versus combined information held by unknown big data compilers in the future. An exponential loss of privacy and hyper-hyperbolic risks in the future for the information sharer are introduced as behavioral economic decision-making fallibilities. For the overconfident information sharer, it remains largely unforeseeable what the sum of the individual information sharing tranches can lead to over time and what information its Gestalt holds for those who have big data insights over time, which can also be analyzed in relation to the general population. Governance gains a critical stance on new media use for guiding on public concerns regarding privacy and information sharing in the digital age (Puaschunder, 2017). While there is some literature on the history of media on politics (Prat & Strömberg, 2013), the wide societal implications of fake news and discounting misinformation has widely been overlooked in contemporary behavioral economics research and the externalities literature. Social sciences literature on privacy and information sharing has to be reconsidered in the age of social media.

The article is structured as follows: An introduction of the theory of utility and communication and information sharing is followed by an outline of the impetus of the digital big data age on privacy. The

first utility theory of information sharing and privacy will be theoretically introduced. Hyperbolic decision making fallibility will become the basis of argumentations around hyper-hyperbolic discounting – the novel argument that information sharing in tranches may lead to an underestimation of the privacy infringements when these bits of information can be put together over time and are compared to big data in order to infer about the individual in relation to the general population.

The subjective additive utility of information-shared tranche by tranche may underestimate the big data holder's advantage to reap benefits from information shared. The discussion introduces problems of the contemporary nudigital society (Puaschunder, 2017), in which big data compilers can reap a surplus value from selling compiled information (The New York Times, November 14, 2017) or manipulate vulnerable population segments based on their previously shared information (The Economist, November 4, 2017). Implications lead to open questions about ethics in the information age and recommendations for a reclaiming of the common good of shared knowledge in education about information sharing in the digital age as well as the democratization of information. Challenging contemporary behavioral insights theory aims at fostering a more informed, self-determined and protected digital society in the wish to uphold e-ethics in the 21st century big data social media era.

BACKGROUND

The wish for communication is inherent in human beings as a distinct feature of humanity. Leaving a written legacy that can inform many generations to come is a humane-unique advancement of society. At the same time, however, privacy is a core human value. People choose what information to share with whom and like to protect some parts of their selves in secrecy. Protecting people's privacy is a codified virtue around the world to uphold the individual's dignity. Yet to this day, no utility theory exists to describe the conflict arising from the individual preference to communicate and the value of privacy.

The Humane Preference for Communication

The act of conveying intended meanings from one entity or group to another through the use of mutually understood signs and semiotic rules is the act of communication. Communication is a key feature of humans, animals and even plants (Witzany, 2012). Steps inherent to all human communication are the formation of communicative motivation and reason, message composition as further internal or technical elaboration on what exactly to express, message encoding, transmission of the encoded message as a sequence of signals using a specific channel or medium, noise sources influencing the quality of signals propagating from the sender to one or more receivers, reception of signals and reassembling of the encoded message from a sequence of received signals, decoding of the reassembled encoded message and interpretation or sense making of the presumed original message (Shannon, 1948). Information sharing implying giving up privacy is at the core of communication. Communication can be verbal and non-verbal. Comprising very many different domains ranging from business, politics, interpersonal, social to mass media; communication is a humane-imbued wish and center core of every functioning society.

In society, language is used to exchange ideas and embody theories of reality. Language is the driver of social progress (Orwell, 1949). Linguists find discourse and information sharing inseparable from socio-economic societal advancement (Fowler, Hodge, Kress & Trew, 1979). Language and communication modes are implicit determinations of social strata (Orwell, 1949). Different institutions and media

sources have different varieties of language and information sharing styles. Access to information is related to social status and market power. Social visibility is a powerful and cheap incentive to make people contribute more to public goods and charities and be less likely to lie, cheat, pollute or be insensitive and antisocial (Ali & Benabou, 2016). Information receipt is an implicit determinant to classify and rank people to assert institutional or personal status in society (Fowler et al., 1979). Mass communication echoes in economic cycles in the creation of booms and busts (Puaschunder, work in progress). Media is also a hallmark of propaganda and political control (Besley & Prat, 2006; Prat & Strömberg, 2013). At the same time, privacy is a human virtue around the world.

Privacy as a Human Virtue

Privacy is the ability of an individual or group to seclude themselves, or information about themselves, and thereby share information about themselves selectively. The right to privacy grants the ability to choose which information about parts of the self can be accessed by others and to control the extent, manner and timing of the use of those parts we choose to disclose. Privacy comprises of the right to be let alone, the option to limit the access others have to one's personal information and secrecy as the option to conceal any information about oneself (Solove, 2008).

The degree of privacy varies in autonomy levels throughout individualistic and collectivism cultures. While the boundaries and contents protected and what is considered as private differ widely among cultures and individuals, the common sense in the world is that some parts of the self should be protected as private.

Privacy has a valued feature of being something inherently special or sensitive to a person, which can create value and specialty if shared with only a selected person or group. The domain of privacy partially overlaps with security, confidentiality and secrecy, which are codified and legally protected throughout the world, mainly in privacy laws but also in natural laws of virtues of integrity and dignity. Privacy is seen as a collective core human value and fundamental human right, which is upheld in constitutions around the world¹ (Johnson, 2009; Warren & Brandeis, 1890).

In personal relations, privacy can be voluntarily sacrificed, normally in exchange for reciprocity and perceived benefits. Sharing private information can breed trust and bestow meaningfulness to social relations. Giving up privacy holds risks of uncertainty and losses, which are undescribed in economics and in particular the behavioral economics literature on intertemporal decision-making (Gaudeul & Giannetti, 2017). People tend to be more willing to voluntarily sacrifice privacy if the data gatherer is seen to be transparent as to what information is gathered and how the information will be used (Oulasvirta, Suomalainen, Hamari, Lampinen & Karvonen, 2014). Privacy as a prerequisite for the development of a sense of self-identity is a core of humanness (Altman, 1975). Privacy is often protected to avoid discrimination, manipulation, exploitation, embarrassment and risks of reputational losses, for instance, in the domains of body parts, home and property, general information of private financial situations, medical records, political affiliation, religious denomination, thoughts, feelings and identity.

Technological shocks have a history of challenging privacy standards (Warren & Brandeis, 1890). The age of instant messaging and big data, however, has leveraged the idea of privacy to another dimension. The concept of information privacy has become more significant as more systems controlling big data appear in the digital age. With advances in big data, face recognition, automated license plate readers and other tracking technologies, the upholding privacy and anonymity has become increasingly expensive and the cost is more opaque than ever before (Ali & Benabou, 2016).

Privacy in The Digital Big Data Era

The amount of big data stored each second has reached an all time high in the digital era. Internet privacy is the ability to determine what information one reveals or withholds about oneself over the internet, who has access to personal information and for what purpose one's information may be used. Privacy laws in many countries have started to adapt to changes in technology in order to cope with unprecedented constant information surveillance possibilities, big data storage opportunities and computational power peaks. For instance, Microsoft reports that 75 percent of U.S. recruiters and human-resource professionals use online data about candidates, often using information provided by search engines, social-network sites, photo and video sharing tools, personal web appearances like websites and blogs, as well as Twitter.

Social media tools have become large-scale factories with unpaid labor (Puaschunder, 2017). For instance, Facebook accounts for the largest social-network site with nearly 1,490 million members, who upload over 4.75 billion pieces of content about their lives and that of others daily. The accuracy of this information also appears questionable, with about 83.09 million accounts assumed to be fake. Aside from directly observable information, social media sites can also easily track browsing logs and patterns, search queries or secondary information giving inferences about sexual orientation, political and religious views, race, substance use, intelligence and overall personality, mental status, individual views and preferences (Kosinski, Bachrach, Stillwell, Kohli & Graepel, in press; Kosinski, Stillwell & Graepel, 2013).

As for the unprecedented possibilities to collect data, store big data and aggregate information that can be compared to big data Gestalt over time and society, privacy has leveraged into one of the most fragile areas of concern in the electronic age, demanding for legal protection, regulatory control and e-ethics (Flaherty, 1989). Today, the existing global privacy rights framework in the digital age has been criticized to be incoherent, inefficient and in need for revision. Global privacy protection shields are demanded to be established. Yet to this day, there is no economic framework on information sharing and privacy control. While – for instance – Posner (1981) criticizes privacy for concealing information, which reduces market efficiency; Lessig (2006) advocates for regulated online privacy. As of now we lack a behavioral decision making frame to explain the privacy paradox of the individual predicament between the humane-imbued preference to communicate and information share versus value of privacy. We have no behavioral economics description of inconsistencies and moderator variables in the decision between online information sharing behavior and retroactive preference reversal preferences in the eye of privacy concerns in the digital big data era.

A UTILITY THEORY OF INFORMATION SHARING AND PRIVACY

Building on classical utility theory, individuals are constantly evaluating competing choice options. Individuals weight alternative options based on their expected utility derived. Indifference curves would then connect points on a graph representing different quantities of two goods, between which an individual is indifferent.

In the case of the privacy paradox of information sharing preferences and privacy values, a person would weights whether or not to share information s or choose the information to remain private p . The respective indifference curves would outline how much of information sharing s and privacy p can be enabled to end with the same utility given the budget of overall information held by the decision maker.

Graph 3 represents the respective indifference curves for information sharing s and privacy p . That is, the individual has no preference for one combination or bundle of information sharing or privacy over a different combination of the same curve. All points on the curve hold the same utility for the individual. The indifference curve is therefore the locus of various points of different combinations of privacy and information sharing providing equal utility to her or him. Indifference curves are thereby seen to represent potentially observable behavioral patterns for individuals over information bundles. The indifference curve for information sharing s and privacy p is subject to communication and information constraints, hence all information budgets and communication opportunities. There is only a finite amount of information and there may be environmental conditions determining if people can exchange and share information. As exhibited in graph 1, the indifference curve for information sharing s and privacy p is a straight line given the assumption that information sharing or privacy are substitutes.

Figure 1. Indifference curve (blue line) for information sharing s and privacy p given the total information and communication constraint

Information sharing s

Privacy p

While in classical economics, an individual was believed to always being able to rank any consumption bundles by order of preference (Jevons, 1871);² the indifference curve for information sharing s and privacy p subject to communication and information constraints may feature a hyper-hyperbolic element or temporal dimension. The information share moment may thereby be a reference point. At the moment of the information sharing decision, it may not be foreseeable what the future implication of the information sharing is.

In general, the costs and benefits of communication are assumed as linear subtraction of positive benefits of communication b_c minus the negative consequences of communication c_c . The nature of the problem is intertemporal as information sharers cannot foresee the future implications of their information sharing divided by variance σ (Prat, 2017).

$$\frac{b_c - c_c}{\sigma}. \quad (1)$$

However, the digital social media era has heralded a hyper-hyperbolic discounting fallibility. Individuals have lost oversight of the consequences of their individual information sharing given big data hoarding capabilities, which also allow drawing inferences about the individual in relation to others.

In the digital big data era, information share online may hold unforeseen risks of privacy merchants or social media capitalists that commercialize information reaping hidden benefits from the information provided (Etzioni, 2012; Puaschunder, 2017; The Economist, November 4, 2017). The subjective additive utility of information-shared tranche by tranche may underestimate the big data holder's advantage to reap benefits from information shared given unprecedented data storage and big data computation power advantages of the big data era. Unprecedented computational power and storage opportunities have created the possibility to hoard information over time and put it in context with the rest of the population in order to draw inferences about the information sharer (The New York Times, November 14, 2017). The digital age and era of instant information sharing have therefore heralded problems of individuals who give in their basic humane need for information communication to become vulnerable over time. The big data information holder may thereby benefit from the history of information and the relation of the individual's information in comparison to the general population to an unknown degree given missing e-literacy and transparency. Comparison to the general public may lead to an implicit underrepresentation and hence discrimination of vulnerable groups. For instance, certain groups that may not be represented online will therefore likely face an under-advocacy of their rights and needs.

While regular hyperbolic discounting captures a game theoretical predicament of the self now versus the self later, the information offering more of a Gestalt in the eyes of the big data holder, leverages hyperbolic discounting to a game theory against uncertainty on the end of the big data holder. The hyper-hyperbolic discounting fallibility therefore may describe that at the moment of information sharing, the individual has hardly any grasp what is implied in the giving up of privacy. The individual only focuses on the current moment trade-off between information sharing and privacy upholding, but hardly has any insights what the compiled information over time holds for big data moguls. As for holding computational and storage advantages, the social media big data moguls can form a *Gestalt*, which is more than the sheer sum of the individual information shared, also in comparison to the general populace's data. The shared information can also be resold to companies (Etzioni, 2012; The New York Times, November 14, 2017). In relation to other people's information, the big data moguls can make predictions about their choices and behaviors. Information can also be used for governance purposes, for instance tax compliance and border control mechanisms (Puaschunder, 2017). Some governments have recently used big data to check the accuracy of tax reports but also to detect people's political views when crossing borders (Puaschunder, 2017). Lastly, the use of big data inferences also implies hidden persuasion means – nudging can be turned against innocent information sharers who have no long-term and computational advantage to foresee the impact of the information share (The Economist, November 4, 2017; Puaschunder, 2017).

While behavioral economics hyperbolic discounting theory introduces the idea of time-inconsistency of preferences between an individual now and the same individual in the future; hyper-hyperbolic discounting underlines that in the case of information sharing preferences this fallibility is exacerbated since individuals lose control over their data and big data moguls can reap surplus value from the social media consumer-workers' information sharing and derive information compiled over time and in relation to the general norm to draw inferences about the innocent information sharer. With the modern digital era, all these features open an information sharer versus information reaper divide in the big data age (Puaschunder, 2017).

From the social media big data capitalist view, the information gain of one more person sharing information is exponentially rising. Hence, the marginal utility derived from one more person providing

information is increasing exponentially and disproportionately to the marginally declining costs arising from one more person being added to the already existing social media platform. Communication costs and benefits are assumed to not be additive and separable.

Expected Utility and Subjective Probability in the Digital Big Data Era

In accordance with neo-classical utility theory, decision makers weight alternatives based on the resulting consequences dependent on uncertain aspects of the environment. But in the digital big data era, individuals simply lack an oversight of the consequences of information sharing. Assumptions on preferences of information sharing are skewed leading to an underestimation of the consequences of amalgamated information and private information evaluated in relation to other's data. Assignment of utilities to the consequences are underinflated. The utility of information sharing is thus the underweighted sum of the utilities of the consequences.

Time Preferences

Following the standard neo-classical nomenclature of time preferences among the population, an information sharing preference over time is introduced. Multi-period decision-making addresses that for each time period, another set of preferences for the same options can be expected. The populace may therefore be theoretically categorized into

- (1) *Extreme impatience*: extreme information sharing as the individual values immediate pleasure of information sharing, information is shared without hesitation, impression management may play a role in this.
- (2) *Impatience*: discounting the future impact of information, uninformed information sharing nature. This is the case if an individual shares information although having a hunch that this information sharing may create problems in the future, called the privacy paradox.
- (3) *Eventual impatience*: discounting the future impact of information at some point in the future leads to controlled information sharing, very likely choosing what categories to expose to public.
- (4) *Time perspective*: related to hyper-hyperbolic discounting awareness, individuals may control information sharing, for instance, these individuals may participate in social media only to reap information from others but not contribute additional information beyond what is required. This type has a controlled privacy and is engaged in social media solely to reap benefits of other's information from social media networks.
- (5) *No time preference*: at the present time the individual neither discounts nor overcounts the future with respect to the present, which may be true for individuals who do not at all participate in social media communication and are blasé about information sharing and gaining information on social media,
- (6) *Persistence*: consistent preference structure regarding information sharing may result in informed information sharing with no regrets, and
- (7) *Variety*: consistently varying preference structure regarding information sharing, likely dependent on the content of information shared, may result in information sharing with regrets afterwards. These individuals have no stringent position towards information sharing or privacy preference, likely have categories for what to share and what not. This type varies in information preferences over time and by subject category.

This nomenclature addresses the problem of capturing valid preference structures over time that allow stringent predictions of choice behavior and strategies for future planning (Fishburn, 1968). The nomenclature also highlights that the selection of information sharing or privacy has an impact on our later choices. Addressing this predicament, Klein and Meckling (1958) suggest the best strategy given future uncertainties is to concentrate attention on immediate decisions that lead toward the main objective while preserving a reasonable degree of freedom in future choices. While Strotz (1957) considers the maximization of utility in an additive, discounted form over a continuous-time future and powerful research on hyperbolic discounting has unraveled pre-commitment and consistent planning as means to curb harmful decision-making fallibility. Yet the age of social media generated big data may impose novel hyperbolic discounting fallibility onto the information-sharing individual (Behears, Choi, Laibson, Madrian & Sakong, 2011; Chabris et al., 2008; Koopmans, 1964). Future research may test the reliability and validity of the nomenclature and unravel moderator variables and variances between different populations, e.g., such as age, cultural heritage, gender, etc.

Expected Utility and Subjective Probability

In accordance with neo-classical utility theory, alternatives are weighted based on the resulting consequences dependent on uncertain aspects of the environment. Assumptions on preferences between such alternatives lead to an assignment of utilities to the consequences and to the alternatives plus an assignment of subjective probabilities to the possible states of the environment. The utility of an alternative can therefore be written as a weighted sum of the utilities of the consequences. The weight for any alternative-consequence pair is the subjective probability associated with the states of the environment that yield the given consequence when the given alternative is used (Fishburn, 1968).

Regarding expected utility, the overall expected utility equation for information sharing and privacy reads

$$u = \sum w^* u_s + w^* u_p . \quad (2)$$

whereby w stands for weight, u_s is the utility of information sharing and u_p the utility of privacy.

The weighted expected utility equation reads

$$u(P) = P(x^1) u_s(x^1) + P(x^2) u_p(x^2) , \quad (3)$$

whereby $P(x^1) u_s(x^1)$ is the probability of information sharing utility and $P(x^2) u_p(x^2)$ the probability of privacy.

In the digital age, the utility of privacy is expected to have a marginal exponential value given the exponential rise of utility for the big data holder to reap benefits from data. The more data is held, the more complex relations can be unraveled by the big data holder. Information can be put into context of time and population correlates. While there is a marginally declining cost of an additional social media user using an established social network, there is a disproportionately large social network gain with another person joining for the social network provider, who can reap an excessive exponentially increasing marginal utility of another person joining and sharing another piece of information. Given the absence of any taxation of this gain, social media has leveraged into an IT monopoly (Soros, 2018).

FUTURE RESEARCH DIRECTIONS

The article presented a first theoretical introduction of a utility theory of information sharing and privacy. Potential limitations are that some communication may not be integrated in the framework, such as non-verbal communication or emotional responses. In general information exchange is very heterogeneous and vast international differences are assumed to exist. In addition, in what time communication online and under what circumstances decisions regarding communication and privacy are made, remains a completely undiscussed topic.

As a next research step, a stringent hypotheses testing of the presented problem is recommended. For instance, future research projects featuring a multi-methodological approach will help gain invaluable information about the actual performance and behavior regarding information sharing and privacy upholding. Interaction of individual on social media should be scrutinized in order to derive real-world relevant economic insights for legal and policy making purposes alongside advancing an upcoming scientific field. Following empirical investigations should employ a critical survey of the intersection of analytic and behavioral perspectives to decision making in information sharing. Literature discussion featuring a critical analysis how to improve e-literacy should be coupled with e-education and enhancement of e-ethicity. Research should be directed towards a critical analysis of the application of behavioral economics on hyper-hyperbolic discounting in the digital age. In the behavioral economics domain, both approaches, studying the negative implications of information sharing and decision making to uphold privacy but also finding ways how to train new media users wiser decisions should be explored. Interdisciplinary viewpoints and multi-method research approaches should be covered in the heterodox economics readings but also in a variety of independent individual research projects. Research support and guidance should be targeted at nurturing interdisciplinary research interests on privacy and information sharing in the fields of behavioral economics and public affairs.

More concretely, future studies should define the value that data has to individuals and data sovereignty in the international context. When people share information, they should be informed to consider what the benefit and value from sharing is for them and what the benefit for social media industrialists-capitalists is. The sovereignty of data and the human dignity of privacy should become debated as virtual virtue in the 21st century. Individuals should be informed that sharing data is a personal security risk, if considered to be asked for social media information upon entry of a country.

CONCLUSION

Overall, the presented piece can also serve as a first step towards advocating for education about information sharing in order to curb harmful information sharing discounting fallibility. From legal and governance perspectives, the outlined ideas may stimulate the e-privacy infringement regulations discourse in the pursuit of the greater goals of democratization of information, equality of communication surplus and upheld humane dignity and e-ethics in the big data era.

KEY TERMS AND DEFINITIONS

Information Sharing: Implying giving up privacy is at the core of communication. Communication can be verbal and non-verbal. Comprising very many different domains ranging from business, politics, interpersonal, social to mass media; communication is a humane-imbued wish and center core of every functioning society.

Privacy: Is a core human value as people choose what information to share with whom and like to protect some parts of their selves in secrecy. Protecting people's privacy is a codified virtue around the world to uphold the individual's dignity.

Privacy Laws: In many countries have started to adapt to changes in technology in order to cope with unprecedented constant information surveillance possibilities, big data storage opportunities and computational power peaks.

Social Media Tools: Have become large-scale factories with unpaid labor for information sharing. The accuracy of this information also appears questionable, with about 83.09 million accounts assumed to be fake.

Utility Theory: Is concerned with people's choices and decisions based on preferences and values.

The 2018 Facebook Data Controversy and Technological Alienation

4

Yasmine Khosrowshahi

Wake Forest University, USA

INTRODUCTION

The controversy surrounding the way in which data was obtained and used by a private corporation, Cambridge Analytica, in connection with the US Presidential election of 2016 begs a series of questions and points to the critical connection between Big Data and a variety of fundamental human imperatives such as privacy and freedom of expression amongst others (Cadwalladr and Graham-Harrison, 2018). This chapter uses the issues surrounding the controversy as a point of departure to explore two related issues – first the way in which the “technologically alienated” individual makes technological decisions without being mindful of the consequences of the technological choices and secondly the way in which the alienation can be utilized to obtain detailed information from the structured and unstructured data that makes up the gigantic corpus of Big Data.

The key to the controversy was the fact that a corporation was able to collect information from individuals in a manner where the people of whom data was collected felt that they were unaware of the fact that their data was being collected. What happens after that is important, but the goal of this essay is to examine the claim by individuals, and their representatives that the data collection happened in a surreptitious manner. While, this essay is not meant to condone what happened, but it is to offer an alternative argument that places a great deal of responsibility on individual users of digital systems. It is useful to consider the notion of alienation in this context.

BACKGROUND

Alienation From Technology

The notion of alienation has been a key philosophical construct in thinking of people in societies. The notion of alienation has been a focus of study from many different perspectives. For example, the approaches taken by political economist Karl Marx and by the psychiatrist Sigmund Freud have been some of the more well-known perspectives on the idea of alienation. In the works of Marx¹ and Freud² there was the common theme that alienation involved the distancing between two entities. Thus, Marx argued that the practice of capitalism produces a distance between the laborer and the product of his or her labor. Specifically, Marx was concerned about the way in which the laborer is separated from the profit that is gleaned from the work of the laborer. Working in a time period similar to Marx, Freud, on the other hand, took a different approach to alienation because not only was Freud not interested in a political

DOI: 10.4018/978-1-7998-3479-3.ch032

economic theory but also there was no great urgency in Freud's analysis on reducing alienation. For Freud, alienation was essentially the natural split between the conscious and the subconscious aspects of the human mind, and from the psychoanalytic perspective of alienation, was a part of the evolutionary process of being human and there was no specific question of overcoming this alienation. To Freud, humans were expected to live with a certain degree of alienation which was internal to the human being and an essential part of life. While Marx and Freud have been the two key scholars who have historically been connected with the idea of alienation, others like Erich Fromm³ and Emile Durkheim⁴ have also used and developed notions of alienation to underscore the distance between the human being and society. In most cases the focus has been on identifying the factors that cause the alienation and then finding mechanisms for reducing the alienation to an acceptable level. Eventually, the notion of alienation actually remains a very well-examined notion in psychology, philosophy, politics, and related disciplines and in most cases the emphasis has been on the ways in which the human being is being distanced from events around him or her. In much of the discussions about alienation, thinkers have tried to find ways to reduce the extent of alienation. The desire to reduce the sense of distance between the individual and the surroundings, particularly when alienation is triggered by external forces, is motivated by the fact that the outcome of alienation can be fundamentally painful to the individual. To feel that one is distanced from the surrounding, or to feel unfamiliar and unacknowledged can be a debilitating experience. The sense of loss of control that can emanate being disempowered has been the focus of discussions in politics and economy for a long time and attempts have been made to understand why alienation occurs and how it can be overcome. No wonder, alienation has received so much attention because it is considered to be an unpleasant and abnormal condition because of the uncertainty and anxiety it can produce. Most of the scholars would argue that to be alienated is essentially an uncomfortable feeling.

While this brief review of the understanding of alienation draws from the traditional understanding of the notion of alienation, I use and expand on the idea of alienation to primarily refer to the idea of distancing (Mitra, 2010). To me the notion of alienation is one that produces a distance between the human being and a specific phenomenon. Specifically, the notion of alienation when considered with respect to technology can be considered as follows:

In most cases, the more sophisticated the individual thinks the technology is, the greater is the alienation of the individual from the technology. Within this relationship between technology and alienation the idea of sophistication is two-pronged. On one hand is the measurable sophistication of a tool going, for instance, from the primitive bow and arrow to the Kalashnikov, and on the other hand is the perceived sophistication of the technology, in terms of how the user thinks about the technology. The latter refers to what the individual thinks about a tool often with limited understanding of the tool. Both these aspects of sophistication play a part in the process of alienation but often operate in different ways since the loci of these two forms of sophistication are in different places – in the technology and in the individual. It can be argued that the perception of sophistication is partly based in the level of knowledge the individual has about a specific technology. A technology can appear sophisticated simply because the person using does not know much about the technology and that ignorance creates the aura of heightened sophistication and increased alienation (Mitra, 2012).

The distance can remain unrecognizable and thus unexplored unless an explicit attempt is made to understand the nature of the alienation. Thus, in the analysis that follows in this essay, I am interested in tracing the nature of alienation between people and the technologies that surround them. In the cur-

rent analysis, the focus is on the way the alienated user remained alienated from a tool just because they perceived it to be sophisticated leading to a set of issues that eventually affected the user.

The Situation

The specific situation under consideration came to the public view in the spring of 2018 when it was reported in several media outlets that a private corporation called Cambridge Analytica was able to access data of Facebook users and use that data for many different political purposes that may have affected the outcome of the Presidential election of 2016 in America. It is estimated that nearly 87 million users were affected by the scandal. Staff writers of Forbes magazine explained that the scandal actually started several years back when Facebook exposed the data from millions of users to an academic researcher (DeMars, 2018). That academics researcher, a Russian-American named Aleksandr Kogan, used a quiz app, similar to a personality quiz app Psychometrics Centre made, called “thisisyourdigitallife” (Mer-edith, 2018). The app was used to pull more data from users than they should have been allowed to. The Atlantic Media Company says that 270,000 people installed Kogan’s app on their Facebook account. Just like any Facebook developer then, Kogan was able to access data about those users and their friends (Meyer, 2018). Kogan then sold all the data to Cambridge Analytica (CA) to then use as part of the 2016 US election for marketing and advertising for candidate Trump. Numerous news outlets including the *Al Jazeera*, the *London Observer* and *The New York Times* reported that Cambridge Analytica used the personal information of millions of users to build software to target potential swing voters in political campaigns including in the 2016 election for candidate Donald Trump. The information created messages targeted at users on Facebook. Christopher Wylie, a key player in the scandal, says, “We exploited Facebook to harvest millions of people’s profiles and built models to exploit what we knew about them and target their inner demons. That was the basis the entire company was built on” (Staff, *Al Jazeera*, 2018).

The Analysis

To demonstrate the issue of alienation the first step was to gain a better understanding of the way in which the general public, the users of digital networking systems, interpreted the situation and responded to the situation. The specific method used in the analysis was to create a narrative about the situation from the perspective of everyday users. This approach relies on the narrative paradigm and utilizes narrative analysis to discover the narrative, or the story, that emerges within the users.

The construct of looking at culture, communication and human behavior and beliefs through the lens of a narrative was suggested by the work of Walter Fisher who in turn based his work on earlier scholars who identified the importance of story-telling and narratives in the process of making meaning of everyday life as people operate within the cultural and social spaces that they occupy (see, e.g., Andrews, 1982; MacIntyre, 1981; Ricouer, 1977, 1983, 1984; White, 1984). Fisher suggested, people can operate as a narrative being where the act of creating and articulating a coherent and rational narrative becomes a part of being human. In doing this, the narrative paradigm offers a unique perspective on the way of analyzing and understanding communication, and the way in which people act.

There are many aspects of the narrative paradigm that merit examination in the early Twenty-first Century of Big Data, particularly when the analysis of large data sets seeks to provide an account of how persons come to believe and behave (see, e.g., Kosinski, et. al. 2013).

The process of narrative analysis begins by collecting a corpus of narrative bits – narbs - that can be used to create a narrative and understand the story that emerges within the community of users rep-

resented by the narbs. Very soon after the news about Facebook became public, a topic (hashtag) was created on the micro-blogging site, Twitter, and many users tweeted with the DeleteFacebook hashtag to promote the end of using the digital network platform (Rosenberg, 2018). For the purpose of this essay, the narbs were composed of nearly 11,000 tweets that were collected for that specific hashtag. The tweets were collected, and the content of the tweets were then analyzed to extract a narrative map which is a visual representation of a narrative. In the analysis offered here, the automated text analysis using the SPSS Text Analytics tool is coupled with contextualizing of the dictionary and offering an intermediary step that mimics the traditional coding process of earlier textual analysis allowing for the recognition and incorporation of the context under which the unstructured big data has been produced, as demonstrated in Figure 1.

Figure 1. Narrative map of the categories extracted from the narbs

The Story

The narrative codes also explain the relationship among categories that were spoken about with a negative affect directly linked to it on the map. The triangle for users, Facebook, and negative affect validates the point that users had a negative affect towards Facebook after the scandal broke out. The lines show a strong relationship between users and negative affect and user and Facebook but a weak relationship between Facebook and negative affect. This indicates that the focus is around the users more than Facebook. Many sources discuss what Facebook did to users, not stating a negative or positive affect but rather just an understanding of how it took users information. This fits the triangle and if there are sources written about this relationship then many of the tweets extracted must have done the same. It is also clear that the triangles that negative affect create are all connected with users as well. Therefore, Internet bill of rights, data, Ad Revenue, and profit all create triangles individually with user and negative affect to show that users are negatively affected by each of these categories. Here again, the users, whose tweets are the basis of the narrative map, deflect attention from themselves to everything else around the use of the Facebook platform without concern for the fact that the alienation of the user also plays a role in the event that occurred.

Negative affect seems to be the category with the most relationships and interconnectedness on the map. The strongest of which is the triangle for FB trackers, attentiveness, and negative affect discussed above. What is also clear in the narrative is the fact that there is no connection between negative affect and Zuckerberg, which suggests that, in this narrative, there is no negative affect for Zuckerberg. While many categories had negative affects however, many categories had an equal amount of positive and negative affects. There were also many other categories such as users, Facebook, privacy, and attentiveness that had both positive and negative affects indicating that for many categories, there were split feelings and opinions.

In addition to the thickness of the lines indicating a stronger relationship, the size of the circle also indicates the number of narbs the category has. For instance, negative affect has the largest circle on the map, meaning there are the most narbs for that category. Aside from negative affect, Facebook Tracker, attentiveness, and Facebook all have larger circles than the rest of the categories and these are the categories talked about most. Most of the categories on the map have the same size circle and same line thickness which means that they are equally all talked about in regard to the hashtag. It is clear that negative affect and its relationship with the categories, especially Facebook Tracker and attentiveness, are the most spoken about.

Another interesting triangle is the connection with users, Zuckerberg, and Facebook. Since the Facebook scandal, many users have blamed the founder of Facebook, Mark Zuckerberg, thus it would make sense that there would be a correlation among the three categories. In addition, since Zuckerberg went in front of the American Congress, there was even more talk about him in relation to users and Facebook. It even seems as if the lines should be thicker from much discussion about the relationship among these three categories. Many articles and sources have surfaced regarding the situation in front of congress. Facebook even streamed it live however this narrative indicates that there was not a strong connection with Zuckerberg, Facebook, and users. Eventually the question that is most important in the context of this essay is the degree to which the users were alienated from the technology, and how that alienation has an effect on the way responsibility is attributed. In other words, “who is to blame” for this event.

Who to Blame?

An important aspect of the narrative is the shifting of the blame for the incident to outside entities, especially the Facebook application and its developer and promoter. As indicated in the story, the users

do not consider the fact that there was a lack of understanding, and therefore an alienation, on the part of the user. There is a strong negative affect about the process of being tracked, and a negative opinion about the need to be attentive to the process of being tracked. It is only after the fact that the scandal happened, when the data was collected, that there appears to be a strong connection between the need to be attentive and the annoyance about that need. This is what is considered to be alienation, where the user gets distant from the tool, continues to use the tool, and it nearly disappears from sight, i.e., becomes ubiquitous (Weiser, 1991). At that point, the user is so alienated from the tool, that the user is inattentive and expects that the tool is working as the user wants it to work. It is only, when the tool “breaks” that the user suddenly becomes aware of the tool, and its accessories, such as the “FB Trackers,” and report a negative affect about it.

The fact remains that the trackers have been around for a long period of time, and will continue to be around in the future, and the alienated user will again become inattentive until the next crisis happens. It is precisely this alienation, and consequent inattentiveness, that allows systems such as Facebook collect data about the alienated user. The example of the event from the Facebook crisis drew attention to the fact that data is collected pervasively and constantly by the digital systems that the users continue to use. Indeed, it can be argued that the growth in the amount of data – and the consequent focus on “Big Data” – is voluminous, grows at great velocity and contains highly granulated details. Yet, the users are alienated from the process of data collection because of the process has receded from sight, and happens “under the hood,” and the users continue to provide the data so that the overall “engine” of the essential digital systems continue to benefit the user. Just as a user can remain alienated from the exact way in which a car operates, but can effectively drive the car, the users of the digital systems can effectively navigate around an online banking system while being alienated from the process that they are using to access the system and the amount of data that they are providing the system. Only when that data is breached does the user become concerned, and as demonstrated in this essay, shifts the blame to the data collection and management process without acknowledging the intrinsic responsibility of the user to be mindful of the way in which the technology operates.

A final crucial aspect of the combination of the alienation and increase in user-generated data that is available for use as in the case of the Facebook incident is the fact that the everyday material practices, from purchasing a bar of soap from a distribution outlet that sells soap from a virtual shop, to playing a game provided by digital social networking platform such as Facebook, have become intimately integrated into the fabric of “everyday life” for most people in the developed and developing World. There is an inescapable pervasiveness to this process that set the foundation for the Facebook crisis. It is only a matter of time before other such critical matters happen where the need for convenience and to increase the efficiency of processes ubiquitous tools are deployed which can eventually be compromised. For instance, one of the largest digital/social experiment has been the creation of a biometric database of over one billion people in India. The system allowed for great conveniences – from opening a bank account to obtaining a cell phone connection – all with a finger print scanner. Yet, the question will have to be settled how the narrative would develop and circulate following reports that the data has been compromised (Khaira, et. al., 2018; Whittaker, 2018). Consequently, using the experience of the Facebook crisis, and anticipating similar events in the future, it is useful to consider some ways in which the user must negotiate the essential terrain of existing in a system where the “real” person is already and always converted as a part of Big Data.

SOLUTIONS AND RECOMMENDATIONS

The emerging data environment and the issues highlighted here, first requires a reconsideration of the tension between the need for mindfulness of one's data-related actions and the expectation that one has the freedom to "speak" and the speech may not be misused. The data suggests that among those who belong to the group who tweeted there was a negative affect towards the need for being attentive. The underlying theme is that one should not have to be continuously mindful about every data-related action. Indeed, the data suggests that users feel that the transparency of the technology should encourage a sense of alienation, and that alienation should not be a cause for concern. Having to be mindful of data-related actions is not considered to be a comfortable condition. For example, users of search engines should not have to be concerned about what they are searching for, even though the search engine is constantly gathering information about the search terms that are being used by a registered user of the search engine who is not conducting the searches under the protection of digital anonymity by using special tools that allow for that anonymity. The very fact that someone may use such anonymizing tools demonstrates a reduced alienation and greater mindfulness. Most users do not do that but rely on another central construct of open-market, democratic system that operate within a stated rule of law often based on seminal documents such as a constitution that is the fountainhead of the laws of the land.

Most countries that are based on constitutional laws attempt to grant its citizens some degree of freedom of speech with sufficient guarantee that what one says would not be the reason of harm being brought to the person. For instance, since the adoption of the First Amendment to the American Constitution the notion of freedom of speech has gone through many iterations through the history of the United States, however, the statements of Supreme Court Judge Thurgood Marshall in 1972 very clearly laid out the principles the concept of freedom of speech as, "To permit the continued building of our politics and culture, and to assure self-fulfillment for each individual, our people are guaranteed the right to express any thought, free from government censorship. The essence of this forbidden censorship is content control. Any restriction on expressive activity because of its content would completely undercut the 'profound national commitment to the principle that debate on public issues should be uninhibited, robust, and wide-open.'" This is fundamentally what many people in the USA, and people in other countries with similar principles, believe to be their right, allowing for the alienation and the luxury to be less attentive. However, the notion of freedom of speech alters in the environment when the speech is recorded pervasively and permanently by entities other than the government. These are private institutions that offer the forum for the speech: such as the ability to propagate a micro-blog, place a comment on digital social network, or obtain entertainment by the use of a digital game. This forum is no longer the legendary "Speaker's Corner" in Hyde Park of London, or the University quadrangles across the USA. On the other hand, the forums of digital speech are owned by private corporations who, within legal boundaries, can utilize the speech of individuals in a manner that will be profitable for the institution that offers the forum. This is a new institution, albeit non-governmental, that is a player in the way most people speak today, and quite different from the environment within which Justice Marshall spoke in 1972.

The data in this study, and in other such examples available endlessly in popular media, suggests that the users who are annoyed about the need for attentiveness are still operating within the 1970s paradigm of freedom of speech with the ensuing tension with the need for mindfulness. The resolution of this tension lies in greater mindfulness about the way in which one expresses oneself, especially about oneself, within the digital forums that are owned by private corporations that has a greater interest in advancing the institution's mission, and profit, as opposed to the original principles that motivated the

need to protect the freedom of speech. This recommendation is the point of entry into the second key recommendation related to the way in which privacy of information needs to be reconsidered.

The rapid digitization of information and the willingness with which alienated users of tools such as Facebook have volunteered personal information to the institutions calls into question the way the alienated user views the overall notion of digital privacy. In spite of the many different ways in which privacy has been considered through the ages, there is some agreement that privacy relates to protection. Privacy suggests that people are interested in protecting some aspects of their lives from the public domain and restrict the access of information to the domains specified by the user. Several American laws codify this notion of protection, with the best known one being the HIPAA Privacy Rule enacted by the United States Department of Health and Human Services in 1996 with the aim of protecting the health information that is held by corporate health service providers. Most Americans rely on HIPAA to protect the health information, and therefore remain unconcerned about the privacy of that data, which too has been copiously digitized. As such, there are domains, such as health, where there is a well enunciated statement and assumption of privacy. This, however, is still not true for other domains such digital social networks. It is true that the level of “intimacy” of the information may not be as sensitive as in the case of health data, but the user needs to recognize that the data is not as well protected as in the case of the health data or data that is protected by other laws such the Family Educational Rights and Privacy Act (FERPA) in the case of educational records. It is important to recognize that the presumptions of privacy cannot be applied universally to all digital data.

The findings from this study leads to a recommendation where the user needs to be aware of what data is protected and to what extent so that the user is able to anticipate what may happen if that data were to be exposed to the public domain. This attentiveness to the variability in the privacy of the data is crucial to deciding what a user volunteers to do in terms of sharing data on digital social networks.

FUTURE RESEARCH DIRECTIONS

The challenges with data breaches and the threat to privacy continue unabated as there is growing evidence that the “trusted” systems are not as well protected as users imagine them to be⁶. In addition to the situation examined in this essay, just with Facebook, there have been ongoing issues such as the stealth of millions of “tokens” in the period starting from July 2017 where personal information of users could have been compromised because users were getting used to the ubiquity of “always logged on” state of Facebook and affiliated applications. Although the crisis was precipitated by gaps in the Facebook security system, part of the responsibility also lay with the way in which the users were routinely, without much attentiveness, were enjoying the convenience of not having to log out or not having to memorize multiple credentials. It is imperative that there be ongoing exploration on two fronts.

First, there needs to be a better understanding of the security protocols and the terms and conditions imposed by private corporations in relation to the data of private individuals. This research requires the engagement of technologists and engineers as well as legal professionals. However, this avenue of research would also benefit from the contributions of scholars who explore the ethical components of how private corporations choose to utilize data for the benefit of the corporation. There is little knowledge, from ethical and sociological perspectives, about the way in which a fair balance is achieved between the competing demands of corporate profit and the expectations of privacy on the part of those who choose to use the products provided by the private corporations.

The second focus of research needs to examine the technological knowledge, attitudes and expectations of the user of digital products. In particular, such exploration ought to examine how alienated have the users become from the increasingly ubiquitous technologies, and what they feel about the tools and what their expectations are with respect to issues such as the right to speak and the right to privacy. The attitudinal studies need to focus on the ways in which the notions of voluntary data revelation and the feelings about the ways in which users think that data ought to be used.

In combination, the findings from such ongoing research can help to first build better informed regulatory processes as well as to develop messages and training for the user to allow the users to be better informed about the way in which data is gathered, managed and utilized.

CONCLUSION

There is no indication that three processes will slow down in the near future – 1) voluntary disclosure of data to private corporations without much attention to the process or its consequences, 2) increasing use of corporate platforms such as Facebook to make everyday interaction with the digital World more convenient and 3) the temptation by legitimate and illegitimate entities to gain access to the data. These three forces are all displayed at work in the study described in this essay. The methodological approach offers a unique way to understand the users and offers narrative information that allows for a deeper understanding of the motives and feelings of the users. It is ultimately what the users feel about the issues of convenience, freedom of expression, expectations of privacy and the consequent user activism and demands that will shape the way in which the three forces interact with each other and eventually find a provisional balance.

KEY TERMS AND DEFINITIONS

Big Data: An increasingly popular term that refers to the large amount of digital data that is being accumulated about individuals, where the data is voluminous, collected at great velocity and extremely variegated in detail offering a nearly precise identity narrative of the individual.

Data Breach: A process where large amounts of private data, mostly about individuals, becomes illegally available to people who should not have access to the information.

Identity: The defining elements of an individual composed of items such as age, gender, race as well as the attitudes, opinions, and beliefs of a person.

Narbs: Narbs are little bits of narrative which exist as fragments of information that are almost meaningless in isolation. But when connected together those trace elements of the story produce an identity narrative of an individual (see www.narbs.info).

Narrative: This is the technical term for a story. Humans are story-telling beings and stories offer a way to make sense of the World around us as well as get an understanding of the people who surround us.

Narrative Map: The maps are made up of specific nodes and connectors. The nodes represent attitudes, concepts, behaviors and different issues that people are talking about in their narbs. The map connects the nodal narbs to indicate how strongly nodes are related to each other.

Technological Alienation: Refers to the process where people get distanced from the technology that surrounds them and the tools that they use; the process has led to the development of a law of technological alienation: as technology gets more sophisticated the user perceives it as complicated and gets alienated from the technology (Mitra, 2010).

ENDNOTES

¹ The ideas of alienation are best developed in a series of notes that were never formally published and was called the *Economic and Philosophic Manuscripts* of 1844. The idea of alienation was most carefully developed in these manuscripts and was later included in Marx's best-known work called *Capital* first published in 1867 and thereafter published in many different languages.

² The idea of alienation as developed by Freud appears in his best-known work called *Civilization and Its Discontents* that was first published in 1930 in German and thereafter has become a widely published work in many different languages including a version published by Penguin Books.

³ Erich Fromm developed and published on his take on alienation in the 1955 book called *The Sane Society* that was published by Henry Holt and Company.

- ⁴ The idea of alienation was developed by Durkheim in his book called *Suicide* published in French in 1897, and available now in many different languages including an English version published in 2007 by Penguin Classics.
- ⁵ As stated on the Website www.themediawatch.com, narrative maps are produced from analysis of narbs, where the maps are made up of specific nodes and connectors. The nodes represent attitudes, concepts, behaviors and different issues that people are talking about in their narbs. For instance, a common node is “positive opinion” which could be made up of positively affected terms such as “like,” “love,” “good,” etc. Similarly, another node could be “immigration” referring to the issue. The map connects nodes together to indicate how strongly two nodes are related to each other. For instance, a dark line between two nodes would show a strong relationship between the nodes, suggesting people are talking about two things simultaneously, almost “in the same breath!”
- ⁶ The incident described here is merely the “tip of the iceberg” in terms of data breaches. In 2018 alone, Business Insider reported that there were 21 data breaches that included major corporations such as British Airways, Google+, Marriott Hotels, and the nation-wide database system developed in India called the Aadhar card (Leskin, 2018).

Forensic Acquisition Methods for Cloud Computing Environments

Diane Barrett

Bloomsburg University of Pennsylvania, USA

INTRODUCTION

Cloud computing environments add an inherent layer of complication to a digital forensic investigation. The content of this article explores current forensic acquisition processes, how current processes need to be modified for cloud investigations, and what new acquisition methods can help when it is necessary to garner evidence from a cloud computing based environment. The article is based on an expert panel Delphi study. The purpose of the qualitative Delphi study was to develop a robust contingency framework for deciding when to use traditional forensic investigative practices, when to use modified processes, and when it is necessary to develop new forensic investigative processes more appropriate to the cloud computing environment.

The lack of previous research on how current methods of forensic acquisition processes apply to cloud computing environments has created a gap that may hinder the continued growth of the digital forensics field. In order to garner a true picture of the application of forensic acquisition processes in cloud computing environments, querying a panel of subject matter experts (SMEs) provided the best possible information.

A section will be included that provides a recommendation on how to acquire evidence from cloud based environments while maintaining chain of custody. A final section will include recommendations for additional areas of research in the area of investigating cloud computing environments and acquiring cloud computing based evidence.

BACKGROUND

Cloud Computing Environments

Cloud computing is encompassed in the capabilities of almost all existing technologies. The cloud market is growing at a rate of 20 percent to 25 percent a year, and reached a size of \$127 billion dollars in 2018. Approximately 30 percent of worldwide enterprise applications are offered via the cloud (Kathuria, Mann, Khuntia, Saldanha, & Kauffman, 2018). The concept behind cloud computing is a production environment in which resources and software services do not function locally. Instead, the Internet or the internal network of an organization seamlessly connects numerous host machines running on a virtualized platform (Skemp, 2019).

Joe-Wong and Sen (2018) provide a general layered architecture of cloud infrastructures as a basic model by classifying the architecture into three abstract layers using two models: deployment and service, along with a set of characteristics. The layers from the bottom up are infrastructure, platform, and application. The infrastructure layer provides fundamental computing resources such as processing, storage,

DOI: 10.4018/978-1-7998-3479-3.ch033

and networks. The platform layer delivers higher-level services and abstractions for integration of the ability to perform application functions in the environment. The application layer allows the capability for applications as a service (AaaS).

These three layers are further broken down into service models, deployment models, and attributes. The three well-recognized cloud service models are infrastructure as a service (IaaS), platform as a service (PaaS), and software as a service (SaaS). The four cloud deployment models are community, hybrid, public, and private. The attributes consist of measured and on-demand self-service, resource pooling, rapid elasticity, and broad network access. This is the exact layered architecture outlined by National Institute of Standards and Technology (NIST) in the final issuance of the cloud computing definition dated September 2011.

Environmental Variables

By 2015, as more and more businesses began to sign on as users, Amazon, Microsoft and International Business Machines Corporation (IBM) had all created cloud computing services. Since then, the popularity of cloud computing has increased because organizations are attracted by the affordability, accessibility, and flexibility of the services (Skemp, 2019). The ability to produce dynamic business environments by using cloud computing environments allow organizations of all sizes to respond rapidly to market changes and pursue creative resource saving solutions. Cloud computing environments offer unrestricted scalability and lower data-center setup costs by using multitenancy.

The multitenancy and virtualization characteristics of a cloud computing environment present difficult implementation demands in the areas of security and access control (Fatima, & Ahmad, 2019). The unique security and access control challenges presented by the use of multitenancy and virtualization in cloud computing environments exist because many individual environments share the same set of hardware. The sharing of storage blocks can result in the accidental and unauthorized flow of information (Fatima, & Ahmad, 2019). The diversity of services offered in cloud computing environments requires variable levels of granularity when implementing access control mechanisms. The risk of resource exploitation by unauthorized users is significantly increased when there are insufficient or untrustworthy authorization mechanisms implemented in a cloud computing environment (Chaudhary & Siddique, 2017).

Cloud computing environments offer many organizational benefits by providing scalability and elasticity but come with complex computing infrastructures. Every cloud deployment and service model instance is different. For example, one SaaS implementation can be completely different from the next. There are many challenges associated with the use of cloud computing environments and existing issues are only beginning to be addressed. As more and more businesses move to a cloud computing environment, automated service provisioning, virtual machine migration, server consolidation, and security are topics that have garnered the attention of the research community.

Digital Evidence Seizure

Digital forensics focuses on the retrieval and analysis of data found on digital devices relative to some type of unauthorized or criminal activity. Traditional digital forensics processes consist of crime scene evidence collection, evidence preservation, evidence analysis, and presentation of the analysis results (Mansour, 2016).

Current traditional digital acquisition processes include maintaining chain of custody control of forensic evidence data. This chain of custody control occurs in the evidence collection phase through the imaging of a system (Shah, Saleem, & Zulqarnain, 2017).

Cloud computing technology disrupts the initial step of evidence collection in conducting a digital forensic investigation. One of the main drawbacks is data acquisition (Monsour, 2016). Traditionally, the seizure of forensic evidence occurs through a search warrant or other legal request. In a cloud computing environment, the emphasis is on the cloud provider contract as opposed to a search warrant or legal request because the data can be geographically disbursed, is under the control of the service provider, and data are spread out amongst numerous servers and other components (Fatima, & Ahmad 2019). In some cases, the forensic investigator never gets to acquire the evidence. The designated employee at the service provider or the cloud broker performs the evidence acquisition and supplies the information to the client, who then sends the information to the investigator (Pichan, Lazarescu, & Soh, 2015). This is contrary to traditional forensic practice where legal documents provide the case investigator the ability to acquire the evidence.

When a crime happens, the location of recoverable data includes the client machine, the equipment of the Internet Service Provider (ISP), the cloud service provider equipment, and the data backups of the cloud service provider. This makes acquiring evidence from a crime committed in a cloud computing environment much more difficult since the environment is not localized like it is in a traditional digital forensic evidence acquisition (Arford, E. 2017). Traditional imaging cannot be performed because it is not possible to take down and create a forensic image of such a large environment.

The digital forensics discipline faces quite a few challenges where cloud computing is concerned especially during the acquisition phase (Mansour, 2016). Traditional forensic evidence acquisition processes do not fit well into cloud computing because of the way cloud computing works. Traditional digital forensic acquisition processes focus on individual computers and isolated environments, while cloud computing forensic acquisition processes include the intricacies of complex infrastructures including virtual servers, applications, and diverse operating platforms that may be located in foreign countries (Burney, Asif, & Abbas, 2016).

Common forensic procedure is to shut down the system in order to take a forensic image of the system. This procedure cannot apply to hosted cloud services due to disruption of service to a wide scope of users. Cloud computing systems consist of multiple user environments, using a variety of services. Shutting down a cloud computing system disrupts services to all the user environments hosted on the system.

When the user or service provider shuts down the virtual machine because of inactivity, service providers reallocate the storage space originally allocated to the virtual machine to other virtual machines (Chaudhary & Siddique, 2017). Upon deletion of the virtual machine and the overwriting of storage space, the evidence disappears. Although it is possible to recover forensic data from a running virtual machine, if the files associated with the virtual machine are not collected, valuable evidence is missed. Associated virtual machine files contain information such as configurations settings and memory content are often not collected as part of the acquisition process.

One of the most commonly used commercial cloud services is Amazon Elastic Compute Cloud (EC2). Hosting cloud services on geographically diverse servers using distributed file systems provides scalability and reliability but present forensics challenges (Alqahtany, S., Clarke, N., Furnell, S., & Reich, C. (2015). Forensic analysis of distributed file systems is difficult (Teing, Dehghantanha, & Choo, 2017). Multi-national web-based organizations such as Facebook and Yahoo use the Hadoop file system. Hadoop is a common distributed file system used in large data environments such as cloud computing. Due to the way the Hadoop file system works, it processes petabytes of data and erasure of forensic evidence could easily go without notice (Teing et al., 2017). The development of Hadoop occurred with fast processing of data in mind and there was very little consideration given to security or forensic analysis capabilities.

CLOUD ACQUISITION PROCESSES

Without a clear understanding of how cloud computing works and the underlying infrastructure components, law enforcement agencies cannot properly investigate cloud computing environments. Some forensic practitioners have taken the view that the acquisition of evidence from the cloud is merely an extension of existing actions used to acquire data from a network because the cloud data is stored similar to network data (Adams, 2013). Contrary to this view, there are differences between cloud computing forensics and network forensics. The primary similarities and differences between cloud computing forensics and network forensics stem from the key areas of physical access, logical access, segregation of evidence, methodology, and legal considerations.

There was no prior research conducted on this subject. In order to garner practitioner opinions on cloud forensics and the application of traditional forensic acquisition methods to cloud forensic environments, an expert panel Delphi study was conducted. The Delphi method provides a means to refine a group consensus opinion from expert practitioners using a sequence of question rounds. Expert panel member selection was based on the criteria from a submitted statement of qualifications. Only digital forensic investigators with at least five years of relevant field experience, published work, industry presentations, and recognition were eligible to participate in this study. The expert panel consisted of 14 members from several countries.

An online written narrative interview questionnaire for the study began with 10 open-ended written questions on cloud computing based on the cloud study by Ruan Baggili, Carthy, & Kechadi (2011). Panel members were then asked to evaluate 20 common forensic procedures for applicability to cloud computing environments. The common forensic procedures selected are shown in Figure 1.

The findings demonstrated there were very diverse opinions on cloud computing, cloud forensics, and the effect cloud computing environments had on digital forensics. Standard evidence acquisition procedures, federal and local laws, court accepted methods, and the cooperation of the cloud provider were all factors that affected the way a successful forensic acquisition was conducted in a cloud computing environment. The areas of tools, processes, and guidance available for forensic evidence acquisitions in cloud computing were relatively immature.

A recap of the responses to the evaluation of the 20 common forensic procedures for applicability to cloud computing environments indicated several key points. Only 55% of the 20 pre-selected traditional forensic processes were usable for the forensic acquisition of digital evidence in cloud computing environments and the usability of those processes had some limitations. Post-acquisition processes were most suited for application in cloud computing environments. Following post-acquisition processes in order of applicability were live acquisition processes. The main limitation in this area was access to the cloud server in order to perform the processes. The results analysis suggested this category of processes had solutions for digital evidence acquisitions in cloud computing environments because the processes were modeled after already established network forensic processes. Thirty-five percent of the 20 pre-selected traditional forensic processes were modifiable for the forensic acquisition of digital evidence in cloud computing environments depending on the level of access and service provider cooperation. Pre-acquisition processes were most suited for modification in cloud computing environments. Five percent of the 20 pre-selected traditional forensic processes required the development of new processes for the forensic acquisition of digital evidence in cloud computing environments. The panel members suggested that pursuing the development of new processes in some cases was moot because the processes were irrelevant to cloud computing environments.

The panel experts agreed that current acquisition processes in the category of dead drive acquisitions did not fit into cloud computing environments and many of the processes should no longer be included because they were not applicable or modifiable.

Fifty-seven percent of the panel members identified remote access as a theme; while many of the remaining members argued that cloud computing does not always involve remote access as in a hybrid cloud. The panel members identified three main characteristics of defining cloud forensics. Verification of data integrity, working with service providers to obtain required information and legal admissibility, and international cooperation were the three main characteristics.

CLOUD ACQUISITION APPROACHES

Ruan, Carthy, and Kechadi (2012) proposed that cloud forensics is a subsection of network forensics and a cross-discipline between cloud computing and digital forensics, adopting the same definitions of cloud computing and digital forensics provided by NIST. The methodology used originates at three distinct dimensions: legal, technical, and organizational. Choosing this methodology encompasses jurisdictional issues, the lack of international cooperation, and formation of foundational standards and sound policies. Ruan et al. (2012) developed a high-level conceptual model that analyzed the forensic impact of cloud computing environments based on deployment models, service offerings, cloud actor roles, segregation of duties, and forensic artifacts obtainable from the environment. Using log files, network monitoring and investigation of malicious behavior can occur (Tak, Kachhwaha, & Mahia, 2018). This area of cloud forensics has the most research and approaches since log files are readily available in most cases.

Adams (2013) proposed the advanced data acquisition model (ADAM). The model breaks down forensic processes into three main functions derived from analysis of previous models. The actions in the first stage occur upon notification of the scope of work to the investigator. The activities in this stage happen prior to arriving at the incident location. In the next stage, the investigator prepares for the data acquisition upon entry of the incident scene. The final stage consists of acquiring and handling the evidentiary data.

Adams (2013) used a distinctions, systems, relationships, and perspectives (DSRP) thinking patterns in creating ADAM, tying scientific thinking to the forensic processes. Initial testing of ADAM compared ADAM to the processes used in three previous investigations. The results produced a viable model. Cases in Australia and New Zealand are using process flowcharts as a manner in which to help the jury and court understand scientific forensic evidence. Widiyasono, Riadi, and Luthfi, (2016) conducted and documented an investigation on the services of private cloud computing using the ADAM method. The methodology applied to a private cloud environment worked well and is a viable methodology for this type of environment.

Shende (2010) approached the digital investigations of cloud computing environments as the mapping of computational and storage structures falling within the investigative scope. Emphasizing the cross boundaries of responsibility and access, service level agreements play a large part in the ability to investigate a cloud computing environment. The key to data access in cloud computing investigations lies in the dialogue between the organization and cloud service vendor in establishing incident response requirements, processes, and protocols when drafting a service level agreement (SLA) (Shende, 2010).

Lu, Lin, Liang, and Shen (2010) proposed using a secure source structure based on the bilinear pairing technique to deliver reliable digital forensic evidence in cloud computing environments. Using a cloud computing architecture comprised of a cloud service provider (SP), a trusted system manager (SM),

and an enterprise size user environment, the secure provenance SP method demonstrates confidentiality of information, authorized access, anonymous authentication, and ownership tracking. Extending this method for forensic use provides ownership information associated with every version of a document to the SM. The SM then uses an ownership-tracking algorithm to follow the evidence to a unique user identity. This proposed design encompasses a wide range of security features, making it ideal for use in the forensic investigation of cloud computing environments.

Wittek and Daranyi (2012) took an approach similar to Lu et al. (2010), in that the work focused on the tracking of digital assets. Using a digital preservation (DP) policy methodology ensures that digital objects remain valid over an extended time period. Cloud computing infrastructure provides a platform ad-hoc computation along with distributed digital preservation. Wittek and Daranyi (2012) proposed a middleware solution in the business services layer of the Sustaining Heritage Access through Multivalent Archiving (SHAMAN) core infrastructure. The business layer serves as the intermediary between the top presentation layer and the lower infrastructure layer. The proposed solution has promising future implications for digital preservation.

Haque, S., Atkison, T. (2018) devised a forensic enabled data provenance model for public cloud in which a cloud auditor is added to the environment and basically performs analysis on the cloud services and provides feedback. This methodology has already been implemented in a more basic model for monitoring cloud elements.

More recently, researchers have been concentrating on separate areas for cloud evidence. Burney, Abbas, & Mumahhad, (2016) took an approach that divides the evidence acquisition process by the cloud environment. For example, a computer forensics investigator can get instance access to log history of the compromised system in SaaS and PaaS service models whereas in IaaS model an image of Virtual Machine can be taken for investigation.

Cooperative storage cloud forensic is relatively new and is just beginning to be explored. Teing, Dehghantanha, Choo, Dargahi, & Conti, (2017) have formulated processes for cooperative storage based on client side analysis while Ho, Kao, and Wu (2018) approach cloud forensics by using timestamp pattern identification.

MAINTAINING CHAIN OF CUSTODY

The most important element in the digital forensics is to maintain the integrity and the chain of custody of the digital evidence. A break in the chain of custody simply means that the case is lost in a court of law (Simou, Kalloniatis, Gritzalis, & Mouratidis, 2016).

Cloud environments are difficult to access in a forensic manner because its environment is live and the evidence cannot be logged into directly as it violates preserving the state of data and alters the data state. This can be compared to looking through a hard drive to find evidence without first creating a forensic image of the drive. The first rule of evidence is to never work on original evidence.

A cloud based investigation may include many cloud components including cloud based email, cloud based personal storage, social media, and cloud based corporate storage. The evidence items can encompass personal e-mail accounts, Facebook pages, corporate storage buckets on Amazon Web Services (AWS), and personal storage on DropBox, Box, and Google Drive. Privacy and legal considerations are a main concern since some of the storage buckets may be located in foreign countries.

Using an investigative environment consisting of a virtual machine (VM) that contains several forensic tools such as Access Data's FTK imager, F-Response Universal, and Paraben's E3 DS, evidence

was able to be acquired while maintaining chain of custody. Tools such as Paraben E3 and F-Response access the cloud environment through an authentication API. Basically the tools act as an intermediary between the forensic examiner and the cloud environment. This allows evidence to be mounted as read-only and prevents direct access by the examiner. Then standard validation processes such as hashing can be conducted. This is an acceptable process from a forensic standpoint. The process does not allow the investigator to touch the original evidence, reinforcing proper forensic procedures. An API-centric approach to tool development yields forensically sound results that far exceed the type of information available by client-side

Analysis (Roussev, Ahmed, Barreto, McCulley, & Shanmughan, 2016).

Once the environment is accessed, both F-Response Universal, and Paraben's E3 DS can compress, hash, and export the data. The evidence is preserved in a forensic manner using this process. Once the acquisition is complete, the evidence is analyzed in the same manner as any other evidence. This validates the expert panel findings that post-acquisition processes were most suited for application in cloud computing environments. Cloud acquired evidence is analyzed in the same manner as any other acquisition. This process is supported by prior research from the 14-member expert panel survey. There are a few important points worth mentioning. Credentials are needed in order to access the environment. The authentication of the accounts require logins and passwords. Authentication keys are required to access AWS storage. As long as all parties are cooperative this information will be available. If the parties are not cooperative, the process cannot be used. When parties are not cooperative, any investigation is impeded, whether it is a cloud-based or a traditional forensic based investigation. When two-factor authentication is used, the process will be difficult as currently tools are not set-up to access information when two-factor authentication is required. This difficulty is encountered whether it is a cloud-based or a traditional forensic based investigation. Privacy and legal issues are a consideration, especially since the passage of General Data Protection Regulation (GDPR).

SOLUTIONS

The fundamental issue in this study was the effect on information technology digital forensic acquisition processes by organizational adoption of cloud computing technology. The study methodology used to develop a new forensic choice set consisting of information-contingent plans for choosing actions based on the uncertainty of information was conceptual and based on existing frameworks. The resulting framework offers a realistic view of cloud computing environment variables that allows forensic acquisition process decisions to be made without making prior assumptions that traditional forensic processes must apply. The contingencies examined are the NIST defined cloud computing service and deployment models applied to current forensic acquisition processes.

The basis for the underlying theoretical application associated with the research study relied on contingency theory to provide a framework for determining when to use traditional forensics acquisition processes, when to use modified processes, and when the development of new methods is required for forensic evidence acquisitions in cloud computing environments. The applicable theoretical framework used in linking this study to other information security research using contingency theory was the framework proposed by Austin and Devin (2009). The research extends the analytical framework of Austin and Devin (2009) by creating a framework for cloud computing forensic acquisition processes based on the contingency framework for determining when to use plan-based methods and when to use agile methods.

The main agenda in doing this research was bringing a framework based on subject matter expert opinions to the attention of forensic examiners on the applicability of current forensics evidence acquisition procedures to cloud computing environments. Since there is a lack of knowledge and understanding about the applicability of forensic evidence acquisition processes in cloud computing environments by examiners, the goal was to provide enlightenment in this area, making forensics investigations more productive and the prosecution of criminal activity more likely.

FUTURE RESEARCH DIRECTIONS

The opportunity exists for researchers to make innovative contributions and have a substantial impact on the cloud computing industry. One of the significant contributions of the panel study is the identification of contingency factors such as available tools, access, availability, and acquisition scope as the underlying elements when choosing the application of digital forensic methods to cloud computing environments. These contingency factors are easily ported to other evidence acquisition methods for expanding research in cloud forensics since there are such diverse environments. Research can be conducted on the development of new processes where multitenancy and physical access are concerned. Setting new standards and best practices when these conditions exist will be difficult for digital forensic practitioners because other parties must be relied upon to provide evidence. There are ample opportunities available to study specific identified deployment models, service offerings, and obtainable forensic artifact areas.

CONCLUSION

The article is based on an expert panel Delphi study. The purpose of the qualitative Delphi study was to develop a robust contingency framework for deciding when to use traditional forensic acquisition practices, when to use modified processes, and when it is necessary to develop new forensic acquisition processes through the evaluation of 20 conventionally recognized forensic acquisition processes by a panel of SMEs.

The study findings indicate that cloud investigations encompass many evidence items. As an industry, digital forensics is beginning to formulate proper acquisition processes of digital evidence in cloud computing environments. Many of the digital acquisition processes that apply to cloud computing environments are modeled after already established network forensic processes. The privacy and legal considerations associated with cloud-based evidence must be addressed. In setting standards for proper acquisition of forensic evidence in cloud computing environments, organizations must create legal requirement documentation encompassing both vendor contracts and the organization. After the legal requirements are set, digital forensic practitioners have the availability to set best practices, but those best practices will be contingent upon the environment and existing conditions. Tools for cloud-based evidence acquisitions that are different from traditional digital forensic tools are now being developed.

KEY TERMS AND DEFINITIONS

Cloud Computing: Cloud computing is an environment in which the Internet or the internal network of an organization seamlessly connects numerous host machines running on a virtualized platform to provide resources and software services.

Digital Forensics: Digital forensics is the division of forensic science that focuses on investigating and analyzing information artifacts located on digital devices involved in computer crime cases.

Elasticity: Elasticity is the dynamic allocation of cloud resources so that an organization can use the exact amount of resources required during any given time period.

Infrastructure as a Service (IaaS): IaaS is an Internet delivered virtual environment in which the service provider supplies cloud infrastructure services that can include software, hardware, and networking equipment.

Multitenancy: Multitenancy is a software architecture in which one server hosts a multitude of different virtual environments for unrelated organizations, or tenants.

Platform as a Service (PaaS): PaaS is an Internet delivered virtual environment in which the service provider supplies cloud platform services that include the operating system and other platform-associated services.

Service-Level Agreement (SLA): An SLA is a binding contract between service providers and purchasing organizations that specifies the service parameters and recourse if an unexpected business interruption occurs.

Software as a Service (SaaS): SaaS is an Internet delivered virtual environment in which the service provider supplies commercial applications, eliminating associated purchasing and installation costs for the organization.

Virtual or Virtualized: Virtual or virtualized is a term used to explain the process of running an environment other than the native computing environment.

Threats and Vulnerabilities of Mobile Applications

INTRODUCTION

Today's mobile smartphones are very powerful, and many mobile applications use wireless multimedia communication. The attack faced by the mobile phones are increasing day by day. The downloadable mobile application has many types of security issues. Malicious apps look like fine in downloadable sites, but they specially designed to commit an attack. Application-based threats may generally be fit into the following categories: Malware, Spyware, Physical Threats, and Vulnerable Application. Malware is a software that performs a malicious action when it is installed without your knowledge. It can even make changes to your phone bill and also an attacker can gain control over it. Spyware is mainly designed to collect all the private information of the system without your knowledge. It specifically targets the browsing history, contact list, user location, email, etc. Privacy threats are somewhat similar to Spyware, but it gathers sensitive information rather than performing their action. Vulnerable applications allow an attacker to access sensitive information, perform undesirable actions, stop service from functioning correctly, or download apps to your device without your knowledge. As mobile devices are constantly connected to the internet and frequently used to access web-based services, web-based threats will cause persistent issues for mobile devices. Then server-side attacks to mobile devices are also increasing, any communication that happens between the application and the user outside the mobile phones happens through a server. Thus, this becomes a primary target that gets exploited by hackers. Some common reasons for this are small security budgets, lack of security knowledge in a new language, too much dependability on the mobile OS for security updates and responsibility, and vulnerabilities due to cross-platform development and compilation. The easiest way to overcome this server vulnerability is to scan mobile devices. Other vulnerable components of the mobile devices are incorrect permission setting that allows access to controlled functions such as the camera or GPS, and obfuscation where functionality or processing capabilities are hidden or obscured from the used emails, email addresses, and attached data and malformed SMS causing devices to crash. Sometimes untested mobile applications also cause the attack to the device, that is the users tend to download apps from third-party vendors instead of downloading from the app store; many of these apps don't have a clear source and becomes vulnerable due to the coding errors, which are not updated enough to prevent exploitation. The excessive power consumption applications are also vulnerable to the mobile devices that run continuously in the background, that drain the battery thereby reducing the system availability.

DOI: 10.4018/978-1-7998-3479-3.ch034

BACKGROUND

Based on the research, the chapter shows that the major attacks are phishing attacks, attacks based on the use of phone cameras, and a screenshot attack “capture me”. By this threat of the mobile application, the user credentials are stolen by an attacker. Several recent works have studied the issue of obtaining private information on smartphones using multimedia devices such as microphones and cameras if the camera is affected by malicious software. Moreover, most of the users have the impression that smartphones are just the phones installed with a variety of software and don’t think of them as handheld computers that are more vulnerable to cyber-attacks. A recent survey reported that 267,259 malware-infected apps have been found, among which 254,158 reside on the Android platform (Daojing, 2015). It also suggested that the number of malware in apps has increased by 614% since 2012. The wide use of smart devices (phones and tablets) encourage the financial institution to consider mobile banking applications as a necessary service to their clients. This issue should be addressed by both preventive approaches and effective detection techniques. For preventing, the application developer should ensure this app by policies governing secure coding and privacy, which do not access any unnecessary information. Then the App market administrator should strictly verify every uploaded application and remove the suspicious app. Detecting techniques are based on signature-based or anomaly-based. In signature-based, the malware is identified by comparing the signatures with the known signature, and in anomaly-based, the normal behavior of the system is monitored and it checks for deviations from the normal behavior.

THREATS

In information security, a threat is a danger or a possibility for an attack that might exploit a vulnerability to breach the security system and therefore cause huge damage to the system. It can be either intentional or accidental. As the population of smartphone users is rapidly increased, the hackers are targeting mobile phones, which have a wide variety of applications. There are many types of threats that are classified as application-based, web-based, and server-side threats (Delac, 2017).

APPLICATION-BASED THREATS

The number of malware, spyware has been increased in mobile devices by more than 600% since 2012, with over 250,000 malware in the Android operating system alone (Daojing 2015). The malware is malicious software that refers to viruses, worms, Trojan horses, ransomware, which cause the deviation from the normal behavior of the system. The malware has many types of malicious behaviors which include leaking sensitive data or stealing credentials, restricting device usage, mobile distributed denial of service, etc. The recent malware is the root exploits (jailbreak exploits) by which the attacker gain access privileges. In mobile, the official application stores such as Google Play and Apple App Store will scan the application they offer for traces of malware, spyware, and remove the application if any threat is detected. The main threat lies in application installation and application handling in mobile devices. The security of the mobile users won’t end once an application has been installed, then the user is asked to make a decision regarding the security and privacy while handling the application. Moreover, it will ask the user for permission to access the information in the mobile device. The application installed are tends to update automatically, in that time it can even change the permission settings, which become a major threat.

Threats in the Android Platform

The devices which use the Android operating system are popular with the customers. Malware attack is the biggest problem we are facing in the android platform. The risk of threat has become so high, the devices that access the internet are subjected to attack or infection by Trojans, keyloggers, and other forms of malware and spyware.

Threats in iOS Platform

All Apple users think that their systems are provided with high security, but the reality is iPhone and other Apple mobile devices also become a target for the attacks. In September 2015, one of the most serious threats occurred, when it was discovered a large number of trojanized iOS apps were being hosted on the service (Sheik, 2020). Here the apps were developed using a malicious version of Xcode. In addition to this, the organized apps are capable of receiving commands from C&C servers to carry out phishing attacks. One of the major threats in iOS is jailbreaking, by which the attacker can escalate the privileges by removing the software restrictions imposed by Apple on iOS. It can be done using kernel patches.

Threats in Windows Platform

The mobile devices with Windows OS are used less in numbers when compared with other Android and iOS, due to its compatibility. It also subjected to many types of attacks mainly the command injection attacks thereby stealing the credentials. currently, Microsoft is seeking to unify their applications, which means that many developers are remaking their applications as universal Windows apps as the ROI on maintaining a stand-alone windows phone app is too little. The Windows App Store will have only fewer applications than in android.

WEB-BASED THREATS

In today's world, the mobile device offers a high level of convenience. At any location (office, home, hotel, playground, road, or any place in the world) the mobile user can fulfill their daily needs, including buying, communication searching, selling, entertainment, making payments, etc. through web applications in mobiles. Threats related to such activity is a major concern and it became a serious problem for the mobile users. This extreme level of comfort brought an extreme level of security issues and threats. Some of the web-based threats are described below (Seo, 2011).

Mobile Browsing

The best feature of the mobile device is browsing, which provides the best use of internet applications. Normally in mobiles, the user cannot see the entire web address or the domain address; hence, it is difficult to check whether the URL is secure or not. It becomes a threat to a phishing-related attack.

Multiple User Logging

Due to the progressive growth of social networking sites and single sign-on in the mobile application ecosystem, it has been found that 60% of the applications are insecure due to the use same login credentials for multiple website or applications moreover in mobile devices the user login to the application once, and they never log out mainly in Gmail account, which becomes a serious threat to mobile devices (Khan, 2015) by which the attackers can acquire the credentials and can gain access to a user's profile page.

Client-Side Injection

As mobile devices are accessing the internet for every action there may be a chance of executing the malicious program without the knowledge of the user, it occurs by mobile applications or web browsing client-side injection. There are many types of client-side injection some of them are HTML injection, SQL injection, etc. In this way, any data can be injected.

Improper Session Handling

Session handling is identified as an important security concern for web applications in mobile devices. Improper session handling is a major threat when mobile devices are accessing the internet over any platform. the application with long expiry sessions is often subjected to the attack, especially in a mobile device. This poor management session provides a way for an attacker to unauthorized access by session hijacking

Weak Authentication and Brute Force Attack

Today, almost every application relies on password-based authentication. The who are using this application won't enforce strong passwords and do not provide any security for the application. Thus, the user itself exposes themselves to a host of threats for an attacker. With the brute force attack, the hacker gains the credentials of the user due to the weak authentication mechanism.

Web-Based Threats in Different Mobile Platforms

The possibility of attacks is larger in the mobile devices of Android platforms when compared with other operating systems. In Apple iOS only a few applications are free of cost, and other applications can be used only by paying money; hence, the user will be considered that there can be some security feature in it. Then the Windows and Blackberry OS are rare in usage by the user, but in every platform, the possibility of an attack is increasing day by day.

NETWORK-BASED THREATS

The mobile devices provide the best support to cellular networks and wireless LAN IEEE 802.11. In both the networks, we have different types of threats for mobile users. Some of the network-based threats are described as follows (Razzaq 2013):

Network Exploits

This threat occurs in mobile devices due to the faults in the operating system and other applications in the mobile. When the mobile device is connected to the network, there is a possibility of installing some malicious software on the user's device without the knowledge of the users.

Mobile Network Services

The network provides a lot of services like SMS, MMS, voice call, multimedia transmission, etc. Using these services, the hacker can launch the attack. For example, phishing attack can be launched by the attacker by which he impersonates himself as a legitimate user and communicates with the user.

Wi-Fi Sniffing

It is one of the major threats to wireless technology. Here every device communicating in the wireless medium is a target for the attack. By intercepting the communication (i.e., man in the middle attack) or by simply monitoring the attacker gain access. Then by placing a rogue access point with a strong signal, the hacker can steal sensitive information. Therefore, communication in the wireless medium is a big risk, and unencrypted data can easily be stolen by the attackers.

ATTACKS

The attack on the mobile device occurs due to the vulnerabilities and threats that we have seen before. The attack can occur in three areas they are, in the mobile device, in the network, then finally in the database (Xenakis, 2015). The attacks are broadly classified into active and passive attacks. Active attacks are performed by the malicious nodes. It involves modification of data or the interruption of the communication. The passive attacks involve simply monitoring the communication and traffic analysis. It is difficult to detect the passive attack.

ATTACKS IN MOBILE DEVICES

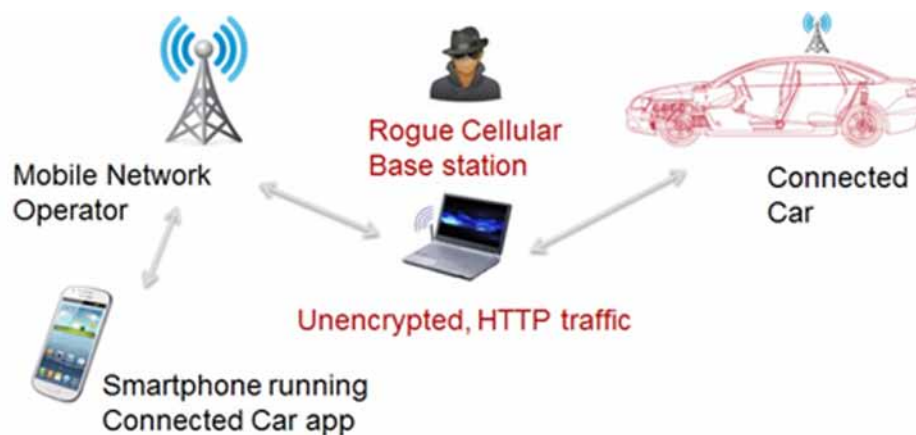

Phishing Attack

The recent years have witnessed that phishing attacks have been increased in the mobile platforms. Mobile phishing is an emerging threat mainly targeting mobile users of financial institutions, online shopping, and social networking companies. This is mainly due to the hardware limitations of mobile devices. It is the type of active attack. Phishing is an identity theft attack online by which the attacker steals the user's credentials resulting in a financial loss as well as a loss to the organization. By the malicious emails, redirecting to the fake websites, impersonation, the attacker can launch the phishing attack. As the mobile device is very compact, and it provides the same functionalities the user moves towards the mobile for all the transaction process. Hence, the attackers targeting mobile devices, for them it is easy to launch the phishing attack on mobile than in desktop systems due to the lack of security systems.

Man-in-the-Middle Attack

This is a kind of active attack in which the attacker sits between the user and the website and steals personal information by breaking the connection between them. Here the attacker impersonates himself as a legitimate user and sends the modified message to the website as it is sent by the legitimate user. This attack is possible even if the message is in an encrypted format. This problem arises when an application fails to use a proper authentication mechanism. Hence, to ensure secure communication, it is important to know how the mobile application performs authentication mechanisms (Mirsky, 2018).

Figure 1. Man-in-the-middle attack

Framing and Clickjacking Attack

Framing is mainly caused by the web browsers like Internet Explorer not checking the destination of the frame. The web framing attacks occur in the browser with the malicious page loading a victim page as an iframe. The common example of framing is clickjacking, where the victim page is loaded which tempts the user to click on that page. This attack enables the wrapper site to execute a clickjacking attack, which is a real threat that has been exploited on high-profile services to steal the credentials of the user or they redirect the users to attacker-controlled sites. The goal of the framing attack is to trick the users into clicking on something different than what they intended. This is mainly to gather confidential information or take control of the affected computer through vulnerabilities. To defend against framing, all the websites use frame busting, which helps to prevent the system from loading a malicious frame in the browser. The new attack called tap-jacking uses the features of the mobile browsers to implement a strong clickjacking attack on mobile phones. The tap jacking illustrates the importance of frame busting on mobile sites. The framing attack can also result in the theft of Wi-Fi passwords or WPA secret key.

Buffer Overflow Attack

The buffer overflow is a common coding mistake by the programmer, which the attacker could exploit to gain access to the system. It is important to understand how the buffer overflow attack occurs and what techniques the attacker uses to successfully exploit these vulnerabilities in the mobile phones.

this attack occurs due to the lack of input validation. The near field communication module of Huawei mobile phones has a buffer overflow vulnerability where the attacker may use an NFC card reader or another device to inject malicious data into a target device. Later Huawei released an update to fix this vulnerability (Bishop, 2012).

Key Concepts

1. This attack occurs when there is more data in the buffer than it can handle; thus, it overwrites the data in the buffer which leads to the loss of information.
2. This attack can even crash the system and create an entry point for a cyber attack.
3. C and C++ are more susceptible to buffer overflow when compared to other programming languages.
4. Secure development or security program practices should include regular testing to detect and fix the buffer overflow attack.

Data Caching

Caching is a technique of storing frequently used data in the memory, such that it could be retrieved easily within a short period. The attack occurs when these data are stolen by the attacker or the attacker can launch the attack by making changes to the cache data which store in the random access memory. Here the attacker replaces the malicious webpage content, code, or some random data he controls to steal the confidential information about the user. Many cache attacks have occurred on Intel X86 CPUs, and the powerful techniques to exploit cache side channels have been developed. However, the modern mobile phones use one or more ARM CPU that have different cache organization and instruction set than in the Intel x86 CPUs. Till now no attack occurs in the non-rooted Android smartphones. But the attacker will try to root the Android smartphone and launch the data caching attack. The routers implement route caching or routing tables to allow faster queries. Then caching in different geographic locations can be seen as content delivery networks (CDN). The CDN is a collection of servers that store local copies of content on servers located strategically across the internet. Each CDN server is a data caching server that provides fast access for the users. Thus, in this way, data caching becomes a major attack that even crashes the server system (Lipp, 2016).

Smishing Attack

This attack is also a security attack similar to the phishing attack but refers to a fraudulent SMS (text message) rather than email. It is a combination of terms of SMS and phishing. Similar to all attacks, the attacker tries to steal personal information. The smishers launch the attack by sending large text messages that are designed to capture the recipient's attention. The messages sent by the attacker provide fake information like "you have won a gift card, visit this webpage to claim it." If the user clicks on this link, then he/she will be directed to the fraudulent website, which will ask you to enter your detail like phone number, email ID. Sometimes it asks for your bank account details. In the smishing attack, the attacker masquerades as a legitimate person to get the user to reveal his/her information. Even the malicious application that is being downloaded from the app store can also cause a smishing attack. The attacker also uses social engineering tactics for convincing the user to do so.

Figure 2. Smishing attack

Improper SSL Validation

The SSL and TLS are widely used protocols for the security purpose. They provide security for the data transmission on the internet between the mobile devices and the remote servers. The SSL/TLS provides end-to-end encryption of the data transmitted, but sometimes it fails to encrypt the sensitive data in which the attack occurs. The mobile devices by nature connect to many different networks and automatically connect to the network. By default it is configured with SSID (service set identifier) for Wi-Fi networks to reduce the traffic. This SSID can be susceptible to man in the middle attack. The basic flow of the SSL handshake is that the client will send a client hello message to the server, and the server will reply will server hello. It is a point in which the certificate validation occurs and also the cryptographic parameter check. In this initialization of SSL itself, there is a possibility of attack that the attacker can steal the secret key shared between client and server. After receiving the server's certificate, the client verifies whether the certificate authority name on the certificate is a trusted CA. If it fails to identify, then the validation fails. Thus, the attacker acts as a legitimate user and uses the services provided by the server (Hinarejos, 2018).

No Encryption/Weak Encryption Algorithm

Different cryptographic algorithms are used in cellular networks. GSM A5/1 algorithm is used for encryption, but it is proved as easily breakable or a weak algorithm. Using eavesdropping itself, the attacker can steal the data. The 3G network provides greater security than the 2G predecessors. It allows the user equipment to authenticate the network and the network will authenticate the device (mutual authentication). 3G network used KASUMI block cipher instead of the older A5/1 stream cipher, but still, several mistakes have been identified in this KASUMI algorithm. Weaknesses in the algorithms used in mobile devices are targeted to the attacks to gather personal information by intercepting the communication.

Privilege Escalation by Mobile Applications

The privilege escalation is an attack of gaining access or privileges to the user's system or a mobile device by exploiting a bug, or configuration in the operating system. The result is that unauthorized

access to the system. Android is a popular open-source mobile platform with prominent features. The weakness in Android's permission mechanism or insecurity leads to privilege escalation attacks. Most of the Android applications are written in Java. They are protected against buffer overflow attacks by bound checking, but can be subjected to attack of a privilege escalation due to the weak security mechanisms. An application with fewer permissions is not restricted to access the components of an application (i.e., it does not ensure the permissions of the device). the privilege escalation can also launch remotely by the attacker, using mail or text message. The iOS platform is also subjected to the same kind of attack as an Android. Mainly in the wireless medium, there will be more possibilities for the attack. Stealing the username and password is also a kind of privilege escalation by which the attacker can compromise a large number of systems. The processing or manipulation of the unknown input leads to this issue.

ATTACKS ON THE NETWORK

Rogue Access Point

The most common attack in the wireless network is a rogue access point, which is nothing but a device deployed by an attacker to hack the information of the users. It can easily be deployed but is difficult to detect. Almost every mobile using the internet is using Wi-Fi, which is nothing but an access point. Thus, the attacker will place a rogue access point (fake access point) with high frequency and strong signal to connect with the user, and as soon as the user connects with a fake wireless access point (WAP), he gets trapped. It may even cause a denial of service attack, malicious data insertion, and data destruction. With this rogue access point, the attacker can do an active and passive attack that we have seen before. According to the report of AirTight out of total access point, 20% are unauthorized in the network, and the users will easily connect to it due to the lack of knowledge about the security threats (Sadip, 2013).

Packet Sniffing

Sniffing is a process of monitoring the activities of a system in the network. When our system is connected to the network, many transmissions will occur. The sniffer, a kind application, can read, monitor, and capture data exchanges and read the data packets. By capturing these packets, the attacker can gather a lot of information about the user by which the attacker can launch the attack. The mobile phones are the major target for the attacker due to the increase in the number of mobile users, and all the users are accessing all the applications in the device itself because of their scalability and convenience. Even the payment process through banking application is also done via mobile devices. Hence, the attacker targets mobile devices rather than the laptop or system, by which the attacker can gather more sensitive information and even the bank account details. All the packet sniffer tools will work only on the rooted mobile devices; therefore, the attacker will first try to root the device before starting to capture the packets. It is also possible to sniff the cellular communication traffic by the attacker, thereby makes the service not available to the users and steal the identity (Mao, 2017).

The tools for packet sniffing in the mobile devices of the android platform are packet capture, FaceNiff, Android Pcap, etc.

Figure 3. tpacket capture tool

Session Hijacking

Session hijacking is an attack of stealing one's valid session or a token to gain unauthorized access to the services in the system. Session hijacking affects the integrity of the data on a network. A network with dynamic nodes or no central administration leads to network attack in which one of them is session hijacking. The combination of a man in the middle attack and denial of service attack is used to launch session hijacking. In session hijacking, the attacker exploits a web session control mechanism, which is normally managed by a session token. The attacker compromises the session token by stealing or predicting a valid session token to gain access. They can steal the session by session sniffing, client-side attacks, and man-in-the-middle attacks. The attacker will predict the session by identifying the pattern of the session token which they gather by sniffing.

DNS Poisoning

The DNS works in such a way that, if the browser needs to visit any website like www.security.com, it needs to find the IP address of the webserver. First, it asks the system's host's file, which may have the IP address of the DNS if it is visited already. Then it asks the external ISP (Internet Service Provider). Normally if we have already visited this site the system has the IP address in its cache itself. Sometimes it will be expired. Here the attacker will steal the cache of the browser and he can change the IP address of the particular DNS, thereby redirecting to the attacker's fake website. Sometimes this attack will lead to the denial of service. The attacker will modify the information in the cache of a server that is part of the domain name system, which leads to a cache poisoning attack. The DNS information has time to live associated with it. To overcome this DNS poisoning, the TTL for DNS information can be specified by the DNS owner to retrieve the DNS information in a short period (Kim, 2011).

SSLStrip

The SSL strip is a type of man in the middle attack in which the website secured with HTTPS is downgraded to HTTP. In SSL strip all the traffic coming from the user's machine is directed towards a proxy website which is created by the attacker. This attack can be done in several ways. Very common methods among them are manually setting up the proxy of the browser to route all the traffic. Then ARP Poisoning, for example, assumes that there is a private connection between the user and the server of a bank, where all the traffic is transferred through a secure tunnel of SSL which has a URL of `https://www.onlinesbi.com`. At this point, the attacker modifies the response from the server from `https` to `HTTP` and sends it to the legitimate user with the URL of `http://www.onlinesbi.com`. Then the attacker can easily gain access to the account, and all the information is transferred from user to server as plaintext as there is no secure connection between them. Hence, the attacker can steal all the sensitive information.

ATTACKS ON THE WEBSERVER

Cross-Site Request Forgery

It is an attack that forces the end-user to perform a malicious action by a click on the website. Thus, the attacker steals the sensitive information of the user. The attacker manipulates the scripts to the web applications to execute based on his/her needs to gather the victim's information. By this attack, the attacker can hijack user sessions, deface a website, and redirect the user to malicious websites. It happens mostly in the web application when the clients have access to the cookies or other authentication mechanisms. The mobile application has a web viewer that will have cookies for its system. The cookies stored in this system can be shared with the applications which lead to a threat of an attack. In mobile platforms especially in Android and iOS, the application will not share their cookies with the other applications. Hence, the possibility of an attack is lesser. It is not likely within the mobile application. The attacker exploits the authentication of the web applications.

Weak Input Validation

Due to the increased users of the internet, many web applications are becoming targets for attack, in which the most common attack is weak input validation. Any web application should satisfy its security features at least to some extent. The application with the script of weak input validation will allow the attacker to gather more information without the knowledge of the admin. The attacker will give any input in the webpage irrespective of the correct value, for example in the phone number field, which should be designed in such a way that it should accept only the integer value, but here the attacker will enter a string. Hence, it produces an error which reveals some information if the validation is not done properly. In the development stage itself, the developer paid only a little attention to the security part. If someone breaks the security of the web application, then only they will think about the security. This kind of behavior of developers is also a threat to this attack, especially in web page design.

Server Misconfiguration

Server configuration is an essential part of web applications. The server misconfiguration attacks exploit the weakness in the web application. Thereby the attacker can bypass the authentication mechanism itself. Enabling the unnecessary services, giving access to the unwanted things, sometimes provides access to the script of the web application and all the exploits of the server misconfiguration attack. All the web applications will have some vulnerabilities due to the server misconfiguration by which the attacker will gain access privileges. Now the attacker has total control the web application he can do an attack on the particular web application.

ATTACKS IN THE DATABASE

SQL Injection

The SQL injection is a malicious code injection attack in the database to steal the information or to crash the database. The attacker uses the input field to steal the data or to gain unauthorized access. It occurs due to the non-validation of the input field. In Android mobile devices, SQLite is used, which is fully functional databases. Here also the attack occurs similar to SQL Server or MySQL. The root cause of the SQL injection is the use of dynamic queries. It is a flaw in the web applications, not in the database or the webserver. Based on the type of application and the way of processing data, the SQL injection can be used to implement attacks like authentication bypass, information disclosure, remote code execution.

Privilege Escalation Attack

Privilege escalation is an attack by which the attacker gains access to mobile devices. It occurs by exploiting the bug or design flaws and weaknesses in security implementation. There are two types of privilege escalation. They are horizontal and vertical. In horizontal privilege escalation, the attacker targets the normal end-user, where the attacker doesn't gain any advanced privileges and simply steals one's identity to gain access. Then in vertical privilege escalation, the attacker gains advanced privileges access to the user account.

DETECTION MECHANISM

All the applications in the mobile will have some vulnerabilities. They should be detected as early as possible to overcome the security issue. Many vulnerability scanners are used in the mobile device that scans for the vulnerability and threats and takes preventive measures. X-ray is a vulnerability scanner tool for the Android platform, and also by analysis methods, we can detect the threats they are static analysis, dynamic analysis, and permission-based analysis (Goel, 2018).

X-Ray Tool

The x-ray tool scans your mobile device to detect vulnerabilities that remain unpatched. After scanning it lists all the vulnerabilities identified in the system and checks for preventive measures. This tool will automatically update to scan for new vulnerabilities.

Figure 4. X-ray scanning tool

Static Analysis

In the static analysis method, the properties of the applications and their source code are inspected or analyzed to detect the threats. However, it is difficult in case of, obfuscation and encrypted techniques embedded in the software. Further, the static analysis is classified into two categories they are behavior-based and signature-based on antivirus.

Dynamic Analysis

The dynamic analysis involves the execution of the application in an isolated environment to track its behavior. In this method, it discloses the normal behavior of malware as executed code. Hence, it is immune to the obfuscation. For suspicious application detection in the Android platform, both static and dynamic analyses should be done. In dynamic analysis, there is also another method called run-time-based behavior dynamic analysis system for Android applications. This system consists of an event detector log monitor and parser. With this collected information, we can detect malicious applications. The tool for dynamic analysis TaintDroid used for system-wide android application by tracking the flow of sensitive information via third-party applications.

Permission-Based Analysis

The permissions requested by the mobile application plays a vital role in providing the access rights. By default, the application won't have any permission to access the data on the mobile. As a user when

we are installing the particular application, allowing that to access the resources. With the help of the listed permission of the applications, we can able to detect the malicious behavior of the application. These permissions can limit application behavior by controlling our privacy. With the static analysis itself, the required permissions can be obtained based on the functionality of the applications such that the insecure applications have been detected by this method of analysis.

PREVENTION MECHANISMS

It is the first line of defense against the attack or a vulnerability in any system. Some of the security guidelines to provide or ensure security for the mobile devices are as follows (Dua, 2014):

- We should do not allow too many applications to install automatically and do not load a large number of applications in the limited memory space and avoid auto-upload of photos to social networks.
- It should perform security and vulnerability assessment of the application architecture.
- Always maintain configuration control and management of the application on the mobile of different platforms.
- The applications should be installed from the trusted application stores.
- In the case of disposing of the device, the data in the device should be securely wiped or deleted.
- Ensure that the Bluetooth and wifi are all turned off by default. And the mobile system should be in such a way that the user should have permission to turn on or off based on their needs.
- Never connect two different networks simultaneously (i.e., wifi and Bluetooth)

Then the user should provide some security mechanisms to defend against the attack they are (Bitton, 2018):

1). Using Password or Passcode:

By configuring a strong password of maximum possible length, which should contain letters, numbers, and special characters for the mobile device, we can provide security for the device. Then set an idle timeout to lock the phone automatically when not in user and enable lockout/wipe feature after a certain number of attempts.

2). Enable Remote Management:

In the enterprise environment, user Mobile Device Management (MDM) software secures, monitors, manages, and supports mobile devices deployed across the organization.

3). Use Remote Wipe Services:

Locating the mobile device or to identify the device at any location by using remote wipe services. It will be helpful when the device is lost or stolen.

4). Update OS and Apps:

Update the operating system whenever the update is available, by which we can reduce the risk of attack. All the applications in the mobile device installed should be updated.

5). Do Not Allow Rooting or Jailbreaking:

Rooting the device will bypass all the security mechanisms, hence rooting, should not be done in the mobile device. Should include this as a mobile security policy.

6). Encrypt Storage:

If there is any mechanism supported to encrypt the storage, configure your mobile device to encrypt its storage with the hardware encryption.

7). Perform Periodic Backup and Synchronization:

The backup should be taken from the mobile device to prevent the loss of data and perform periodic synchronization.

The mobile security policies should be implemented to prevent it from the attack. Then harden the browser permission rules and configure application certification rules, by which mobile devices can be prevented by the attacks. Then some general guidelines for the mobile platform security include:

- Configuring wireless to ask to join networks
- Perform regular software maintenance
- Control the location of backups
- Control device and applications
- Prohibit USB keys
- Encrypt backups
- Prevent local caching of email
- Sandbox application and data

Mobile tracking tools for iOS platform include finding my iPhone, iHound, GadgetTrak iOS security, iLocalis. Then for the Android platform the tools include find my phone, prey, my antitheft, where's my droid.

The mobile security guidelines for the administrator:

- Publish an enterprise policy that specifies the acceptable usage of consumer-grade devices and brings your devices in the enterprise.
- Publish an enterprise policy for the cloud.
- Enable security measures such as antivirus to protect the data in the database.
- Specify a session timeout through the access gateway.
- Specification of the password is also considered by the admin whether the domain password can be cached on the device, or the user must enter it when a request for access.

MOBILE PROTECTION TOOLS

Bullguard Mobile Security Tool

Acts as an antivirus tool and scans for risks in the mobile device and provides security from the attacks.

Figure 5. Bull guard protection tool

Lookout

- It protects the phone from mobile threats.
- Helps in avoiding risky behavior, like connecting to an unsecured wifi network, downloading a malicious app.
- It provides a secure backup of your mobile data.
- It helps you to find your device if it lost or stolen.
- Provides remote management.

Figure 6. lookout protection tool

WISelD

- It provides secure and easy to use encrypted storage for personal data.
- It allows the user to store websites, usernames, and passwords and quickly log on to the particular website through your mobile phone.

Figure 7. wiseid mobile protection tool

zIPS

- Employs machine learning to detect abnormal behavior and isolate your device before any exploit can take place.
- It is equipped with a behavioral analysis engine to automatically detect and block malicious threats by monitoring how they change the characters of the mobile device.
- It scans all the mobile applications and browsers to enhance the security of the user devices and keeps your whole organization safe from MITM, IPv4, and even IPv6 attacks.

Figure 8. zips tool

Firewall and Intrusion Detection System

With the help of firewall and IDS software, we can prevent the mobile device from the attacks. The mobile device is a wireless device hence there exists a higher possibility of an attack when compared with the desktop system. It is better to use a firewall and IDS system to ensure security for mobile devices.

CONCLUSION

The smartphone is becoming more popular in terms of communication, sensor, and for doing any activities online, we can say it replaces all the desktop and laptop systems due to its scalability and portability. Even though it is very small in size, it provides a lot of services such as messaging, browsing, emailing, playing games, and payments. As the services increase in the mobile device, the possibility of the attack also increases. Many new threats, vulnerabilities, and attacks are increased due to its multi-functionality. Here we have discussed the threats and vulnerabilities of the mobile applications, and also the attacks that occur from these threats. Finally, we have discussed the detection and prevention mechanisms and the mobile security tools that are used to protect the mobile device.

FUTURE RESEARCH DIRECTIONS

This chapter provides a detailed description of all the threats and vulnerabilities of the mobile applications that we are using in our day-to-day life. Hence, with this research, we can proceed further to improve the present vulnerable mobile application with the prevention and detection mechanisms and also by providing guidelines for the developers. This may help people to reduce the threat to some extent. Several research works can be done more than this, like the countermeasure for the specific threat to improve the present situation by implementing some new methods. More threats and vulnerabilities other than discussed and can be analyzed to find the countermeasure in the future, such that it may not occur again.

KEY TERMS AND DEFINITIONS

Attacks: An offensive action that targets the system networks, infrastructures, or personal computer devices to steal sensitive information.

Authentication: Process of checking the identity of a person or a device.

Encryption: Process of encoding the information in a different format that can be understood only to authorized persons.

Exploits: Refers to a piece of software that takes advantage of the vulnerability, thereby damaging the whole process of the system. It can occur in both the software and the hardware.

Malware: It is malicious software that can be in any file or a program.

Obfuscation: Deliberate act of creating a machine or a source code that is not understandable for humans.

Ransomware: A type of malware that can deny the accessibility of the system until the ransom is paid.

Security: Refers to the activity of protection for the computer system in terms of usability and integrity. It includes both the hardware and the software.

Spyware: An unwanted software that has the ability of stealing the sensitive data, without your knowledge.

Threat: The uninterpreted event that causes a risk that leads to loss.

Trojan Horses: Refers to a type of malware that seems to be a legitimate application.

Viruses: Malicious code that replicates itself to another program, file, or document, thereby changing the process in the system.

Vulnerability: Refers to a flaw in the computer system, which creates a way open to the attack.

Worms: Similar to viruses, but it replicates itself to spread to the other systems connected to the same network.

Web Authorization Protocols

BACKGROUND

Web applications were designed so to be a simple and friendly way for humans to interact with a machine. Initially, they were custom made and could solve a few problems. However, as the technology evolved, it was possible to create Web applications that could solve an even bigger range of problems. Nowadays, Web applications can virtually do almost anything. Apps are stand-alone applications that implement the full functionality of a Web page/application (Ater, 2017). These apps are typically installed on a mobile device (e.g., a smartphone or a tablet). There are simple but useful applications (e.g., apps that provide information about the weather) and more complicated ones (e.g., the Facebook and the LinkedIn apps). Most of these apps have something in common: They require some sort of account creation in order to personalize the data that they will offer to the user. Of course, this is a major development for apps. In the past, one could select a city and see the weather forecast in detail. One question that comes into our mind is: Why has the weather forecast has been so personalized and why Facebook needs to know my location at any given moment?

Most people are very sensitive about their personal data. Not all people consider the same kind of data, personal. Nevertheless, there are data that are definitely personal. For example, one's location or personal messages are definitely personal data. Apps require some of these personal data in order to provide a fully personalized experience. But this is something that makes people very suspicious. There are two problems here:

- i. How is this information going to be used?
- ii. How can be sure this information will not end up in wrong hands?

Fortunately or unfortunately, in the end, most users give access to their personal data. People do that because they trust their information to apps and whoever is behind them (e.g., a company, a developer, etc.). Typically, people who have “adopted” *stereotypes* (Neil Macrae, Stangor, & Hewstone, 1996), assume that developers have taken every precaution so that an app uses the data in a safe and sound way. Naturally, this is not always the case... Although the data management problem has been relatively easily solved in the past, still there are other more complicated problems that have come up after it. With so many personalized apps, anyone has typically an account for each app that she is using. If someone wants to use n apps, then that person needs n different accounts! [This is a major problem that was examined quite early, for example see (Adams & Sasse, 1999).] Having many accounts implies the use of many *authentication* systems. An authentication system makes sure that when a user attempts to login to a system or an app, she will be granted access only when she enters a valid user name and the

DOI: 10.4018/978-1-7998-3479-3.ch035

corresponding (secret) password. After user authentication, a system proceeds with *user authorization*, which is a process that verifies that the right person has access to the right data. A simple example for the discrimination of authentication and authorization is the following. Consider a student who enters the library. She shows her membership card to the security officer and enters. This procedure can be thought of as an authentication process. Next, the student is searching for a book. She finds the book and takes it to the reading room that is guarded by someone. Our student is asked for her membership card, but her *credentials* are not adequate as the reading room is for teachers only. The second check can be thought of as an authorization procedure. So the problem with many accounts and different authorization systems for a single app is solved with the *authorization protocols*. These protocols give us the ability to use one, two, or more accounts to connect to any number of applications in a secure and safe way. In this article we give an overview of authorization protocols and safe data transfer between apps.

INTRODUCTION

When we hear the term “protocol” what comes first in mind is a number of rules someone has to follow in a certain occasion. These rules have been given by someone who created this protocol and it is considered that these rules, if followed, are the best way to deal with this occasion. For example, think of banquet protocol and how one has to arrive at such an event, how she is supposed to dine, etc. An authorization protocol is definitely a protocol but differs slightly with what we described so far. In particular, a protocol is supposed to be unchanged and strict. However, the authorization protocols are being upgraded every time some security error occurs. We have introduced two new very important terms now: *upgrade* and *security*. The first term, upgrade, shows the flexibility of these protocols and it is being implemented

Figure 1. Authentication process. PR is a reliable partner and OP is an OpenID provider

with new protocols based on the old ones or layers that work along with the protocol. The second term, security, is what it is all about. When someone grants access to an app to his personal data, then one is mainly concerned about the integrity and the security of her data. For example, if a very personal photograph (e.g., one that shows an intimate moment) suddenly becomes public, then this is a security error. Thus we must ensure that these protocols are first of all secure.

Our effort to solve the problem with multiple accounts when using many different apps made it clear that we need authorization protocols. Nowadays, things have changed and we typically have one or maybe two accounts in different Web pages/apps and manage to connect to the rest of our accounts using these two apps. This means that we allow these apps to exchange information and data with the rest of the apps. This is realized in a secure and safe way because the way this exchange happens is controlled by the authorization protocol. This protocol guarantees that the correct information from the correct user will be shared in a safe and secure way with the correct app. In a way, this description is an oversimplification, however, it describes the main idea of authorization protocols and also explains how it works with many and different accounts.

OAuth: An Authorization Protocol

When we create a process in which sensitive data are being exchanged and/or shared, we have to make sure that this is a safe process and take every necessary precaution so not to get compromised. This is the ultimate goal for any authorization protocol, in general, and for OAuth, in particular. From the first moment the OAuth (OAuth Community Site) protocol made publicly available, it has been used widely in software engineering and by computer software companies. Currently, there are two versions. Let us now explain how, at least in theory, OAuth operates. But first, let us introduce some simple terms related to Web programming.

- **Server:** It is a computer program that provides certain Web services to other programs or devices (e.g., think of a Web-mail server).
- **Client:** It is a computer program that is able to use some services provided by a server (e.g., a Web-mail client).
- **End-User:** Typically this is a (real) person that uses a device, a Web page, or a stand-alone computer program.
- **Access Token:** It is a sequence of characters considered as an entity that is used get access to a database or information provided by a server. An access token is not forever valid and expires after some time. When an access token expires, it can be replaced with the *refresh token*.

We are sure that most readers have the opportunity to try to login to a Web page or an app using the credentials they are using for a different Web page or app. Since most people have either Facebook and/or Twitter accounts, when they want to use a new app (e.g., a fitness app), they will be asked to sign up using their Facebook or Twitter account. Of course, users can always choose to create new accounts with new credentials. Suppose that someone chooses to sign in using his Facebook account. Then, the new app will exchange some data with Facebook's site and presto the user is granted access to the new app. What really happened beneath is that the new app has acquired information about the user and is using them to create a new user profile. In this really short time, the client (e.g., the fitness app) and the server (e.g., the Facebook site) are following the OAuth (or OAuth 2.0) protocol in order for the client to obtain from the server the required information. Both the Facebook site and Google mail site are ex-

amples of sites that have used OAuth and now use OAuth 2.0 (Hardt, 2012) in a compatible way. OAuth compatibility is a very important aspect of the authorization process. It ensures that both the client and the server have the necessary tools installed to proceed with the authorization process.

OAuth as an authorization protocol had some great advantages and some security errors. Naturally, the advantages remained in the next generation of the protocol. In addition, most security errors have been fixed in the new version. One of the strong characteristics of OAuth is that each information exchange session is considered unique and since certain security measures are in effect, it is also secure. At this point it is rather important to say that OAuth was not as widely used as the OAuth 2.0 because of the limited demand at that time (it appeared in 2006). Also, the next version, OAuth 2.0, was released a short time after OAuth and it was much better than OAuth. However, since OAuth 2.0 was so widely adopted, many different types of authorization code flow were designed. These different types have been designed so to solve the speed problem (sometimes authorization was painfully slow). They also tried to make instances that work for specific data exchanges that are not so sensitive. Nevertheless, OAuth 2.0 main *grant* (in OAuth parlance types are called grants) is one and it is used in more than 70% of cases. Why? Simply because it is the most secure. This grant is the *authorization code grant* (Authorization Code Grant).

Authorization Code Grant

The main component and most important aspect of this grant is the authorization code. In general, this is a sequence of characters that encode certain kinds of information. It is also unique for every session. These sequences of characters include information about the server and the client and kind of information can be exchanged. This binds them both to an exchange that is safe. The authorization flow follows these steps (see Figure 2):

Figure 2. Abstract Protocol Flow

1. The client gives to the end-user the necessary information in order to proceed with the flow and redirects it to the server in order to authenticate.
2. The End-user authenticates herself with a login page provided by the server.
3. If the End-user authenticates successfully, she is asked if she allows the client to proceed with the information exchange.
4. If she agrees with the information exchange, the server creates an authorization code based on the information that have been given by the client and the information that will be exchanged. The server redirects the End-User back to the client with the authorization code.
5. The client uses the code to authenticate with the server and asks for an access token.
6. The server creates and gives the access token to the client if the authentication process is complete.
7. With this access token the client can now access the information.

From the description of the operation flow of the OAuth 2.0, it should be clear that the authorization code is a secure flow (see Figure 3). It should be also clear that each session is unique as is the exchange of specific information (i.e., one can get the same information from another session).

Figure 3. Authorization Code Flow. Note: The lines illustrating steps (A), (B), and (C) are broken into two parts as they pass through the user-agent

OAuth 2.0 Evolution: Open ID connect

As the use of OAuth 2.0 became widely accepted, many security issues came up. Most of those are not obvious. They can be exploited but this is not a particularly easy task. Common security problems in OAuth 2.0 are happening when the authorization code of session is released or when someone can somehow find a way to obtain these codes. These problems can be solved when the tools that we have used in an

implementation of OAuth 2.0 are the best possible. Unfortunately, in many cases these tools are not used. The reason for this is that it takes time to handle all possible security problems. And by time we mean the time it takes to implement all these additional checks and the fact that these additional checks will make an application quite slow. Thus people always make compromises in order to get an optimal result.

To fix the problem that occurs because of the security issues a new addition to the OAuth 2.0 was created, the Open ID connect (Open ID connect, 2019). This is a layer that works on top of the protocol and fixes the security issues that were created.

Open ID connect or just Open ID is a layer that works on top of OAuth and has as its main component the ID token. This token works in a way that is similar to the way the authorization code works only it is much better. It is a JWT type, where JWT stands for *JSON Web Token*. This is a JSON type token. JSON, the Javascript Object Notation, is an open standard file type that is used for data transfer between a server and other components. The JWT has a certain structure that is composed by three components:

1. The header
2. The payload
3. The signature

Each of these components is created in every session and they are unique, safe and secret. The header contains two pieces of information that are necessary to every JWT and determine the use of the JWT. The payload contains the information that we need to use for authentication and authorization. The signature is the header and the payload is encrypted. Afterwards, the signature is used to encrypt the whole JWT again. The extensive encryption that takes place in the creation of every JWT makes the process reliable and secure. The encryption methods that are used vary and there is no requirement as to which method to use.

The great advantage of using a JWT is that someone can include many pieces of information inside. And this happens because it was opted to use JSON to encode JWTs. The ID token contains information about the client and its authentication. It also contains information about the authentication of the end-user. The information always arrive safe and sound to the server. From there the server can perform the authorization and proceed with the process.

With the use of the Open ID connect all the data exchanges became safe and secure. However, there is a little price to pay because of the process time: encryptions and decryptions are time consuming processes. But the ultimate goal of a secure and safe session is guaranteed so this is the best solution.

FUTURE RESEARCH DIRECTIONS

There are always new challenges one has to face and/or solve when dealing with security and/or authorization. For example, a blogger has noted that “[OAuth 2.0 is] overly prescriptive and, given that there isn’t a single conformant implementation by a major service provider, perhaps too complex for even the big boys” (OAuth 3.0: The Sane and Simple Way To Do It). And this is the reason why people are working on the next version of this protocol. Another similar problem is the use of web banking. People are forced to have an unique web account for the bank accounts they keep in a specific bank. However, if someone has two or even three accounts in two or three banks, then she obviously needs three different web accounts. Clearly, it would be nice to allow users to login with a single account, but of course there many problems that have to be solved before this may happen.

CONCLUSION

Data exchange while using applications is very common nowadays. Securing these processes by making reliably protocols is a top priority. The user will never be able to fully understand how these protocols actually work in the background. Some developers make sure that these protocols are not only secure but they are using only the allowed information and distributing them correctly and safely. There will always be security errors in these processes. What developers are trying to achieve is to minimize the risk of a big data leakage in order to provide reliability and trust to the user.

KEY TERMS AND DEFINITIONS

Exploit: A piece of software that takes advantage of vulnerabilities in applications, networks, or hardware.

JSON (JavaScript Object Notation): Is a lightweight data-interchange format. It is easy for humans to read and write. It is easy for machines to parse and generate.

OAuth: A simple way to publish and interact with protected data.

Open ID Connect: Is a simple identity layer on top of the OAuth 2.0 protocol.

Secure and Reliable Knowledge-Based Intrusion Detection Using Mobile Base Stations in Smart Environments

Department of Computer Applications, SSMRV College, Bangalore, India

INTRODUCTION

Wireless sensor network (Yick, Jennifer, Mukherjee, & Ghosal, 2008) (Akyildiz, F., Su, Sankarasubramaniam, & Cayirci, 2002) is an assembly of low cost nodes which can capable of self-configuration. These nodes communicate with each other forming a convenient topology. Smart home (Erol-Kantarci, Melike, & Mouftah, 2011), military surveillance (Lee, Hyuk, Lee, Song, & Lee, 2009), health monitoring (Kim, et al., 2007), habitat monitoring (Mainwaring, et al., 2002) are some of the applications where these nodes play a primary role. These unsupervised nodes are liable to get compromised and launch different kinds of attacks. Hence the malicious nodes have to be detected (Butun, Ismail, Morgera, & Sankar, 2014) at an early stage to minimize the attacks in the network.

The mobile base station (Sun, Osborne, Xiao, & Guizani, 2007) (Djamel, Khelladi, & Badache, 2005) provides flexibility to the system to move to any corner of the network. They are capable of authenticating the other nodes but they require more security than the static ones. The proposed work is using the mobile base station that adds reliability to the data transmitted. The work is compared with (mehmood, et al., 2018). The work considers two different kinds of nodes in the network. Assistance nodes are the watchdogs in the work. They aid in selection of cluster head and provide information on any malicious activity in the respective cluster. The mobile agent is used in the work to cross-verify the malicious activity of the node deployed in the cluster.

The work is divided into six sections. The section 2 details the work done by various authors. The section 3 explains the proposed work in detail. The role of different deployed nodes is described in this section. Section 4 provides details of analysis of the work. The details of simulation of the work are provided in section 5. Section 6 details the future directions. The work is concluded in section 7.

BACKGROUND

Many authors have provided their own insights (Butun, Ismail, Morgera, & Sankar, 2014) and suggested different ways to detect an intrusion in the sensor network. The details of the same are explained in this section.

In (mehmood, et al., 2018) the network is divided into clusters and each cluster is headed by the cluster head. The base station has a blank knowledge database installed. The cluster heads are provided with inference engines. The heads monitor node-related events and data transmission in the respective clusters. The data monitored is considered as events and the same is transmitted to the base station. This

DOI: 10.4018/978-1-7998-3479-3.ch036

received data is analysed to detect suspicious activity. Routine and redundant events are eliminated and same is notified to the respective cluster heads. The threats detected in the received message are notified to the cluster heads. The same is broadcasted to the other cluster members. Any unknown event is analysed and alerted to the cluster heads to avoid transmission. The cluster head is rotated among the members of the cluster for effective and energy consumption of the nodes.

Three stages are proposed by the authors in (Silva, et al., 2005) to detect an intrusion in the network. Filtered messages are collected by the promiscuous node in data acquisition phase. Using this approach the energy is saved. The array storage structure is used to store the discarded messages. In the rule application phase the rules are applied to stored data in array. If the tested data again results in failure, the data is discarded. The approach reduces detection latency. Failure alert is raised if the stored data does not obey the stated rules. An intrusion detection alert is raised if the failure alert is raised beyond a threshold. The failure history is maintained by the respective node. The previous and the present cumulative failure value are combined to obtain new cumulative value. The approach follows deviation failure.

The authors have suggested a security scheme to detect intrusion in (Onat & Miri, 2005). Node impersonation and its effect are addressed in this work. Node impersonation is where the intruder steals the identification of the legitimate node. It provides itself with the same identity credentials. It gains the trust of the other surrounding nodes and gets into depleting the resources or provides false alarms. In the proposed work data and control packets are directional. Tree based forwarding structure is used to route the packets from one end to another. The anomaly report is generated by the neighbours. If more than one node declares illegitimate activities w.r.t its neighbour, the suspicious node is concluded to be guilty.

A Light weight scheme is proposed by the authors in (Ioannis, Krontiris, Dimitriou, & Freiling, 2007) to detect the illegitimate node in the network. The system is focussed to detect blackhole and selective forwarding attacks based on specification based detection. The watchdogs are into cooperative decision making process where the selective forwarding attack is detected to take appropriate actions. The system is into gaining the information from the neighbouring nodes to ward off the guilty node. The nodes are into auditing and aid in building intrusion treat level. This report is shared to bring in collective report. To achieve the success in detection, four conceptual models are utilized. Local packet monitoring, local detection engine, cooperative detection engine and local response are building and the work is divided among the nodes of the network to increase success rate of detecting intruder.

A game theoretic approach is suggested by authors in (Agah, Das, S. K., & Asadi., 2004) to detect intrusion in the network. The authors have suggested three different approaches to detect the compromised node in the network. In the first approach, attack-defence scenario is created. The sensor nodes and the attacker are in non-cooperative mode. The game achieves Nash equilibrium for the attacker and the Intrusion Detection system. This resultant provides an advantage to the Intrusion detection system. Second scheme Markov decision process is used. The system is into learning mechanism. The Intrusion Detection system observes the system and tries to understand the behaviour of the intruder. Using this analogy it tries to analyse which node requires protection. Third scheme uses intuitive method. The node that has the highest traffic load is given the higher priority of protection.

A hierarchical trust based scheme is proposed by the authors in (Chen, Guo, Bao, & Cho, 2014) to detect intrusion in the network. The nodes are evaluated for their honesty, energy and cooperativeness. Sensor node level and cluster head level trust is maintained in the system. The sensor nodes observe other nodes of the cluster for their legitimacy. The cluster head maintains the trust level of other cluster heads in its vicinity. The trust evaluation based on either direct or indirect methodology. The direct evaluation is evaluated for their activity when they communicate with other nodes of the network. The trust level generated by the nodes of the cluster is exchanged by each other. The trust level related to other cluster

heads is forwarded to the base station. The quality of trust and social trust is considered to derive the trust derivative. Stochastic Petri nets are utilized to derive the analytical model.

Local alert modules are used in the study (Krontiris, Benenson, Giannetsos, Freiling, & Dimitriou, 2009) to enable cooperative intrusion detection procedure. The sensors collaborate to identify the malicious node in the network. Different attacking scenarios with identifying the guilty node are discussed in the work. Five stages are used to identify the illegitimate source. One-way key chain containing an ordered list of cryptographic keys is generated using the hash function. These keys are embedded in the nodes before deployment. The nodes send and receive messages from the alert region. This phase is used to authenticate the communicating party. The nodes are to broadcast their key in publish key phase. The other receiving nodes can verify the legitimacy by checking to regenerate the previous key value. In exposing attacker phase the nodes apply a count value for the suspected list and concludes the node as illegitimate based on collaborative data. The actual guilty node is identified in external ring reinforcement stage.

An intrusion detection system is suggested in (Onat & Miri, 2005) for MANETS. The neighbouring nodes in the network alert each other for anomalies. Nodes are programmed to share unexpected behaviour of their neighbours. The detection algorithm uses packet count based sliding window methodology. Last n packets are used to calculate the statistics to make a comparison with the arriving packets. Arriving time and receiver power is recorder. The neighbour has to confirm the statistics of its neighbouring node. The max and min values are benchmarked to the receiver power. An alert is raised if the receiver power crosses either the max or min receiver power. Comparison threshold rate is calculated and if it crosses a certain boundary, an alarm is triggered.

Two factor user authentication is suggested by the authors in (Das & Lal, 2009) to bring in efficiency. The methodology suggests registering the user with the password followed with query phase. The user utilizes a smart card that aids in authenticating him followed by the login procedure.

The authors in (Rajasegarar, Sutharshan, Leckie, Palaniswami, & Bezdek, 2006) has suggested cluster-based anomaly detection algorithm. Euclidean distance is used as dissimilarity measure between pairs of data. Fixed width clustering algorithm is used in the study. After the formation of clusters outliers are classified. The system uses centralized approach. At certain intervals (time window measurement) the sensors send its data to the gateway. The gateway combines its data set with other received set. The cluster algorithm is implemented on this data. The algorithm used minimizes the communication overhead. K nearest neighbour algorithm is used to detect intrusion. The cluster is identified as anomalous if the average cluster distance is more than one standard deviation of inter-cluster distance. The authors have implemented their algorithm on the sensor data collected from great duck island project.

Inside attacker is detection in this work (Fang, Cheng, & Chen, 2007). Four phases make up the algorithm. In the information collection phase the neighbours observe the other nodes in their vicinity and provide the observation result. Q -component attribute vectors are used to provide the result which is broadcasted to its neighbourhood. Packet sending rate, dropping rate, forwarding delay time and sensor readings are measured. False information filtering phase is where the false information obtained by the neighbourhood is filtered. Trust-based false information filtering protocol is used to filter the false information. Trust value is generated by direct observation. If the value is closer to 1 the node has higher probability to be considered as normal sensor. The trust is calculated according to the degree of deviation from the neighbourhood activities. Outlier detection is the third phase of the algorithm. Distance between the sensor to the centre of set data is computed. The mahalanobis distance is calculated. Using the distance variant the suspicious neighbours are listed. To conclude with the decision majority vote is considered.

Intrusion detection in adhoc system is suggested in (Heiderscheit & D., February 25, 2014). The detection of the intrusion is suggested based on messages received from the source. The location details of the received message are compared to derive the authenticity of the source. If any intrusion is happening the same is portrayed in the extracted location detail information. The work also focuses on the communication of the respective node with various sources. The position extracted is shared with other source. The source communicates with an identifier as the resultant of the communication. If the communicated source will be inconsistent if the shared information is unknown to it.

An intelligent intrusion detection methodology is suggested (Thamilarasu & Geethapriya, 2016) to improve security in wireless body network. A multi-objective genetic algorithm is used to detect the attack. Both mobile and wireless sensor nodes are used in the work. Jamming attacks, random jamming attack and selective forwarding attacks are considered in the work. Total number of detections was measured including positive and negative in the system. Three core metrics are used- detection rate, false positive rate and total energy usage. The metrics is used to address the trade-offs between security and resource overhead. The generic algorithm methodologies are used in the proposed work. This includes selection, recombination, mutation and replacement. An optimal combinational of the feature sets is suggested in the training phase.

Beacon frames emitted by unauthorized devices are monitored in (Rathi, M., Jain, Merchant, & Lin., 2014). The edge devices actively participate sending the probe request to trigger response from the unauthorized devices. The received message is verified against the data maintained by intrusion detection system. The Media access control (MAC) address is verified followed by verification of Service Set Identifier (SSID). The system is capable of monitoring packet information. The edge devices record information and transmit the same to the database for further analysis. After finding the malicious edge, the port is switched to preserve security in the network.

Two intrusion detectors are used in the work (Young-Han, et al., 2014). The first detector transmits the classified packet to the second detector. First network processor and packet header intrusion condition are used to classify the packets. The processor does high speed processing using the micro node. The second detector aims to make detection of the packet payload. Using the intrusion detection outcome intrusive packet and non-intrusive packets are collected for future analysis.

A hybrid intrusion detection model is suggested in (Maleh, Ezzati, Qasmaoui, & Mbida., 2015). The system aims in providing high detection rate and low false positive rate. The work is based on support vector machines (SVM). A set of attacks is considered in the work. The system evaluates the malicious behaviour of the target based on the fixed rule of signatures. Cluster-based approach is adopted to increase the lifespan of the nodes. In the work the cluster head behaves as local base station sensor. Two kinds of monitoring agents are considered in the work. The local agent monitors the data transmitted and accepted by the nodes. The signature database is gradually built by observing and using anomaly detection methodology. This information is shared between the nodes of the network. The global agent is used to monitor the communication between the neighbouring nodes.

Low complexity and energy-aware methodology is suggested in (Sudip, Krishna, & Abraham., 2011). The work is based on sampling. The system is designed where the nodes are unaware of their neighbours. The proposal is based on the assumption that the system has a certain budget configured. The nodes are into continuous sampling stage at the minimum budget. The sampling rate is increased if the detection of the malicious activity is more. Once the detection analysed minimizes the sampling rate is reduced.

PROPOSED WORK

Table 1. Notations Used in the Study

Notations used in the work	Description
N	Network under consideration
BS	Base station
N_i	Node i of the network
S_{in}	Set of inferences
Hello	Hello message
Ack	Acknowledgement
r	Transmission radius
CH_i	Cluster head of cluster i
M_A	Mobile agent
H_A	Hash code generated by the cluster head and the mobile agent
A_i	Assistance node of cluster i
N_{id}	Node identification
L_i	Location information of i node
H_i	Hash code generated by i node of the network

Assumptions Made in the Study

The following are the assumptions made in the study-

- The network contains three types of nodes namely cluster head/cluster member, mobile agent and assistance nodes.
- The base station is the most trustable node in the network. It is the responsibility of the base station to provide a set of behaviours assumed to be normal. These sets of behaviour are fed into the assistance nodes before their deployment.
- The nodes deployed in the network are liable to many kinds of attacks. The nodes are free from the attacks till they form clusters.
- The assistance node is the only watchdog that keeps a watch on other nodes of the network. It that does not communicate with other nodes of the network except the base station.

Working of the System

3.2.1 Nodes Used in the Work

- *Static nodes* – The system has three kinds of static nodes.
 - *Cluster members* -These nodes are responsible to sense the environment, process them and transmit the readings.

- *Cluster heads* – These nodes are responsible to aggregate the readings it receives from the cluster members, remove the duplicates and transmit the resultant to the next available hop.
- *Assistance nodes* – These nodes are the reservoirs of reference data and also act as watch dogs.
- *Mobile nodes* – These nodes are used in the system to provide cross-verification status of the suspicious node.

3.2.2 Deployment of the Nodes and Formation of the Clusters

The nodes are deployed randomly in the form of group. Every group will have an assistance node. After the deployment, the nodes broadcast each other with a hello message and its identification. In notation (1) the node N_i is broadcasting hello message and node identification of itself to the network N .

$$N_i \rightarrow \text{Hello}, N_{id} : N \quad (1)$$

The nodes that are within the transmission radius r will be able to hear the message. The nodes that hear the hello message send the acknowledgement message to the transmitter. In the notation (2) N_j is transmitting the acknowledgement message ack and node identification N_{id} to the node N_i .

$$N_j \rightarrow \text{Ack}, N_{id} : N_i \quad (2)$$

The nodes which are able to transmit and receive message will form a cluster. The cluster head is randomly elected. The assistance node is not elected as the cluster head. It is valued as a library that provides and stores set of observations, inferences and behaviours. It is the responsibility of the cluster head to collect the data, eliminate the duplicates and transmit the resultant message to the next available hop or base station. The cluster head is selected based on the trust value provided by the assistance node.

3.2.3 Role of the Assistance Node

The base station would have embedded set of behaviours assumed to be normal in the assistance nodes. The assistance node provides its trust level only at time of electing the new cluster head. The assistance node also behaves as a watchdog and aids in maintaining the trust level of the cluster members. The assistance nodes watch the behaviour of the nodes in the cluster, and make a comparison to the stored behaviour set. Based on this set it concludes a node is legitimate or illegitimate. If it obtains any suspicion on any of the nodes, it notifies the base station. A hash code is generated by using the location information of itself and the node identification. Let H_i be the hash code generated using the location information L_i and node identification N_{id} . In the equation (3) the node N_i is generating the hash code using the available information.

$$N_i : (L_i, N_{id}) \rightarrow H_i \quad (3)$$

The symmetric key is used to encrypt the notification and the hash code is attached to the message before transmission. In equation (4) the node N_i is transmitting the encrypted message E_i suffixed with hash code H_i to the base station BS.

$$N_i \rightarrow E_i \parallel H_i : BS \quad (4)$$

3.2.4 Role of the Mobile Agent

The base station will be able to obtain a reliable message using this approach. On receiving the message from the assistance node the base station alerts the mobile agent. The mobile agent is sent the location derived from the hash code. In the equation (5) the base station BS is alerting the mobile agent M_A with the location information L_i to confirm the illegitimacy of the suspicious node.

$$BS \rightarrow L_i : M_A \quad (5)$$

On receiving the message the mobile agent goes to that location, for some time interval makes the observation of the suspicious node. After a certain interval, the result is transmitted. It also uses its location to derive the hash code and the symmetric key stored inside it to encrypt the transmission data. The hash code is suffixed to the encrypted data and transmitted. In equation (6) the mobile agent M_A is transmitting the encrypted data E_M suffixed with the hash code H_M and time interval T_A to the base station.

$$M_A \rightarrow E_M \parallel T_A \parallel H_M : BS \quad (6)$$

After confirmation, the base station notifies all the nodes of the cluster and the cluster member is isolated from the group.

ANALYSIS OF THE WORK

The proposed work is designed to trace the guilty node and take appropriate action. The nodes in the network are deployed to sense the environment and provide the readings to base station. The cluster is headed by the cluster head that collects the readings from its cluster members and forwards the same to the next available hop. Every cluster has an assistance node that behaves like a watch dog. This node keeps an eye on all the cluster members. Any unusual activity is notified to the base station. The base station notifies the mobile agent for evaluation of the situation. The mobile agent after continuous observation for certain interval confirms the mobile agent with its message.

Assumption That the Cluster Head is Compromised

The cluster head is responsible to aggregate the sensed data transmitted by its cluster members, eliminate the duplicate ones and transmit the resultant to the next available hop. If the cluster head is assumed to be compromised, it will behave unusually. The compromised node will only concentrate to waste the resources and use the collected data inappropriately. It will not be able to do the following –

- It will not be able to communicate with its cluster members w.r.t time
- It will not actively participate in electing the new cluster head
- It will be randomly sending messages to its neighbouring nodes.
- It will not remove the duplicate messages before transmission.

After certain observation, the assistance node notifies the base station. The mobile agent is sent by the base station for re-evaluation. On receiving the message from the mobile agent the base station notifies the suspicious node and the node is isolated from the cluster. A new cluster head is elected.

Assumption That the Cluster Member is Compromised

The cluster member is responsible to sense the environment, process them and transmit the processed data to the cluster head. If the cluster member is compromised it will not be performing its jobs appropriately –

- It will not actively participate in electing the new cluster head
- It will not be able to communicate with its cluster head w.r.t time
- It will be randomly sending messages to its neighbouring nodes.

The assistance node and mobile agent confirms the status. On positive response the base station notifies the cluster of its activities. The guilty node is isolated from the cluster.

Assumption That the Assistance Node is Compromised

The assistance node provides its trust level only at time of electing the new cluster head. It will not communicate with any other node in the network. Hence in most of the cases it is assumed to be reliable. If in case it is compromised the node it will behave inappropriately-

- It will not be able to generate the hash code using its location and node identification.
- It will involve itself in depleting the energy resource by communicating with other nodes of the network
- It will not be able to provide trust level values during electing the new cluster head.

Other nodes of the cluster if receives any message from the assistance node other than the trust level during election of the cluster head notifies the base station. The base station communicates with the mobile agent and assigns the same as the assistance node.

Assumption that the Mobile Agent is Compromised

The mobile agent is used in the proposed work only to evaluate the node for its guiltiness. The mobile agent can behave inappropriately if compromised-

- It will not follow the orders given by the base station. If the orders are not followed by the mobile agent, the base station after not receiving the message from the same concludes it to be inactive or illegitimate. In either of the cases it messages the other mobile agent to perform the job.
- It will not be able to generate the hash code using its location.
- The location of the mobile agent and the location provided by the assistance node have to be within the radius r . If appropriate message is not obtained, the base station terminates the mobile agent and reassigns the job to a new mobile agent.
- It will involve in transmitting messages to other nodes of the network. Other nodes of the network inform the situation to the base station. The base station after receiving a certain count of messages, broadcast the network of the mobile agent.

SIMULATION

The work is simulated using NS2. Table 2 provides the settings used to simulate the work. The work is simulated in 200m*200m dimension. Around 64 static nodes are utilised to collect data from the environment. The nodes are deployed randomly in the environment. 8 clusters are formed. 3 mobile agents are utilised in the work. Total simulation time considered to draw conclusions of the work is 60s.

Table 2. Representation of the setting used in the simulation

settings used for simulation	Description
Node dimension	200m * 200m
Number of nodes deployed	64
Distribution of nodes	Random
Number of clusters	8
Number of mobile agents	3
Simulation time	60 s
Length of encryption key	164 bits
Length of generated hash code	64 bits
Length of broadcast message from base station	256 bits
Length of message by mobile agent and assistance node	284 bits
Length of trust level information provided by the assistance node	24 bits
Length of node identification	16 bits

Reliability

In (mehmood, et al., 2018) the network is divided into clusters and each cluster is headed by the cluster head. The base station has a blank knowledge database installed. The cluster heads are provided with inference engines. The heads monitor node-related events and data transmission in the respective clusters. The data monitored is considered as events and the same is transmitted to the base station. This received data is analysed to detect suspicious activity. Routine and redundant events are eliminated and same is notified to the respective cluster heads. The threats detected in the received message are notified to the cluster heads. The same is broadcasted to the other cluster members. Any unknown event is analysed and alerted to the cluster heads to avoid transmission. The cluster head is rotated among the members of the cluster for effective and energy consumption of the nodes.

The proposed work improves reliability compared to (mehmood, et al., 2018). The proposed work considers all the nodes liable to get attacked and hence all the nodes deployed are under supervision. The nodes under the suspicion list is notified earlier and the approach increases reliability.

In the proposed work the assistance node is deployed which does not communicate with other nodes of the network. It only provides the trust level value during electing a new cluster head. Hence to a greater extent it can be considered reliable. A node is concluded as guilty only when it displays certain characteristics and the evaluation is done by the assistance node and the mobile agent. Hence compared to the previous work (mehmood, et al., 2018), the proposed work is 7.07% more reliable. The same is represented in the Figure 1. More the reliability of the network, the security (Lou & Kwon, 2006) (Islam, Shen, & Wang., 2012) also increases.

Figure 1. Comparison of the previous work with the proposed work w.r.t reliability of data received

Energy Consumption

Energy is one of the resources which are scarce in the sensors. As these nodes cannot be recharged, caution has to be taken to provide energy conserving algorithms. The proposed work takes the following measures to conserve energy-

- Has adopts Cluster-based routing.
- Duplicate data is eliminated by the cluster head.
- Has adopted Multi-hop routing.
- Only assistance nodes have to behave as watchdog and provide information to the base station. The previous work (mehmood, et al., 2018) makes the cluster head responsible of the notification of the malicious node.
- The cross-verification of messages and evaluation is done more systematically.

Compared to the previous work (mehmood, et al., 2018) the proposed work conserves 12.9% of energy. The comparison w.r.t energy is provided in the Figure 2.

Figure 2. Comparison of previous work to the proposed work w.r.t energy consumption

Security

In (mehmood, et al., 2018) the network is divided into clusters and each cluster is headed by the cluster head. The base station has a blank knowledge database installed. The cluster heads are provided with inference engines. The heads monitor node-related events and data transmission in the respective clusters.

The data monitored is considered as events and the same is transmitted to the base station. This received data is analysed to detect suspicious activity. Routine and redundant events are eliminated and same is notified to the respective cluster heads. The threats detected in the received message are notified to the cluster heads. The same is broadcasted to the other cluster members. Any unknown event is analysed and alerted to the cluster heads to avoid transmission. The cluster head is rotated among the members of the cluster for effective and energy consumption of the nodes.

Comparing with the (mehmood, et al., 2018) the proposed work does not rely on cluster head for monitoring information. The assistance nodes in every cluster provide the regular readings of the monitored activities of the nodes of the cluster. If any suspicion they notify the base station. The base station conveys the same to the mobile agent to cross-verify the notification. On affirmation from the mobile agent, the further action is taken. Comparing to the (mehmood, et al., 2018) the proposed work is more reliable and hence the security level is better by 3.025%. The same is represented in the Figure 3.

Figure 3. Illustration of comparative analysis of data secured in both work

FUTURE RESEARCH DIRECTIONS

The proposed work aims in detecting the malicious node in vicinity, notifying the respective and isolating the same on confirmation. Any malicious activity is detected in the proposed work. The assistance node and mobile node aim in detecting and notifying the base station of the activity of the guilty node. The assistance node notifies its suspicion while the mobile node is used to evaluate the notification. The work can be enhanced by-

- If the cluster happens to be located nearby the base station, the energy consumption will be low on transmission. For long distance located nodes, minimizing the energy consumption made by the assistance node for transmitting the notification to the base station has to be considered.

CONCLUSION

Sensor network are the assembly of tiny devices of homogenous or heterogeneous nature. These nodes are capable of sensing the environment, processing the data and transmitting the same. This unsupervised network is always liable to get attacked. Hence some security measures have to be adopted. In addition attacker detection algorithms aid in better reliability and conservation of resources.

The proposed work aims at bringing reliability and conserving energy of the nodes. The system consists of two types of nodes deployed- Static and dynamic. Static nodes except the assistance node senses

the environment, process it and transmits the same. Cluster-based routing is considered in the work. The cluster head aggregates all the data, eliminates the duplicate ones and transmits to next available hop. The assistance node acts as a reservoir of set of behaviours termed as normal for the node. This node watches the other nodes of the cluster and creates a trust level for each. The procedure aids in choosing reliable cluster head. The assistance node provides a report of any malicious activity in its cluster. This report is verified by the base station and mobile agent is summoned for re-evaluation. On confirmation, the node is isolated. All the deployed nodes are tested for their legitimacy in different ways and by different nodes. Hence the reliability is increased by 7.07%, security is increased by 3.025% and energy is conserved by 12.9% compared to the previous work.

KEY TERMS AND DEFINITIONS

Assistance Node: These are nodes deployed with other nodes in the network to aid the other nodes in their doings.

Cluster-Based Routing: The nodes in the network are grouped together in the form of clusters. The nodes transmit their readings to the group head which later transmits the aggregated data to the next available hop.

Intrusion Detection Scheme: The methodology adopted aids in detecting the compromised nodes in the network.

Knowledge-Based Anomaly IDS: The nodes after certain amount of observation of the network are provided with certain observations that aid them in locating illegitimate nodes.

Mobile Agent: Mobile agents are the set of dynamic nodes capable to moving from one end of the network to another and doing their regular routines similar to static nodes of their calibre.

Smart Environment: Smart environment is an assembly of sensors, actuators and many computational elements providing services for betterment of human life.

Wireless Sensor Network: Wireless sensor network (WSN) refers to a group of spatially dispersed and dedicated sensors deployed to monitor/track any object of interest.

Improved Cross-Layer Detection and Prevention of Sinkhole Attack in WSN

INTRODUCTION

Wireless sensor network (Chen, Makki, Yen, & Pissinou, 2009) (I.Akyildiz, Su, & Sankarasubramanian, 2002) is an assembly of tiny devices which self-configure and communicate in the unsupervised environment. These devices are used in many applications (Xu, 2002). Military surveillance (Lee, Lee, Song, & Lee, 2009), agriculture monitoring (Baggio, 2005), habitat monitoring (Polastre, Szewczyk, Mainwaring, Culler, & Anderson, 2004), smart homes (N.K.Suryadevara & Mukhopadhyay, 2012), hospital surveillance (López, Custodio, & Moreno, 2010) are some of the applications where these devices play a major role in accumulating data without human intervention.

Transmitting confidential information is one of the responsibilities of these devices. While doing so, these devices are liable to get compromised due to their limitations. As these devices are not monitored, the illegitimate nodes and their activities will remain undiscovered. Hence to bring the guilty into light better security measures have to be accommodated. The methodology adopted has to minimize the occurrence of the same by alerting the legitimate nodes of their activity.

Sinkhole attack (Ngai, Liu, & Lyu, 2006) (Rehman, Rehman, & Raheem, 2019) is one such attack where the compromised nodes advertise themselves. They broadcast false hop count to the normal nodes in their vicinity. The attack is launched by the illegitimate node advertising itself as the most favourable path to the base station. Their activity not only attracts the traffic towards itself but also utilizes the network resources. The guilty node after obtaining the trust of its surrounding nodes attracts all the traffic and is liable to launch different kinds of attacks. In the proposed work the solution is provided to minimize sinkhole attack in the network. The proposed work is improving cross-layer design suggested in (S & S, 2017), where Media Access control layer (MAC) and network layer is provided with algorithms to perform. The proposed work is divided into five sections. A detailed literature survey is provided in section 2. The proposed work is explained with detail analysis in section 3. Future research directions are suggested in section 4. The work is concluded in section 5.

BACKGROUND

The proposed work provides solution to tackles and minimizes the occurrences of Sinkhole attack in the network. Many authors have provided their suggestions to tackle the same. This section provides a brief history of the same.

In (Ngai, Liu, & Lyu, 2006) network flow graph is utilized to detect sinkhole attack. The selective forwarding activity is considered to make the detection of the attack. The nodes are monitored to find the missing data from the region. A statistical methodology is adopted to accomplish the task. Using the

DOI: 10.4018/978-1-7998-3479-3.ch037

mean of the data sent and amount of data collected using sliding window a measure is calculated. This calculated value is compared against the threshold to measure the suspicious activity in the respective area. The base station gauges the suspected area. After detecting the affected area the base station forwards a request message to the area. The message contains the IDs of all the affected nodes and is made to move from hop to hop. A timestamp is included in the message to avoid replay of the messages. The respective nodes sign the message with its private key. After receiving the message from the nodes, the receiving reply with the base station with its message. The message contains details of IDs, ID of the next hop and estimated cost [hop-count, data rate]. The base station constructs the tree using the information from the received message. The area under sinkhole attack follows a pattern where all the packets move towards the invaded node. Using this methodology the adversary can be detected.

The authors in (Krontiris, Dimitriou, Giannetsos, & Marios, 2007) have constructed a routing tree to tackle sinkhole attack. The system follows distributed architecture. Identical IDS clients are embedded in the nodes deployed in the network. The IDS agent is responsible for network monitoring, intrusion detection and decision making. The client listens to the network traffic, captures the individual packets and examines the same. The packets in vicinity are scrutinized for legitimacy. A specification based approach is followed by the supervising nodes. A deviation from the normal user defined rules is considered in the detection procedure. The system has to provide appropriate rules to detect suspicious behaviour. Two rules are used in the proposed work. In both the rules the sender field is verified to know its identity. The node ID has to be one of the neighbours and not the examining node. A cooperative mutual conclusion approach is followed to conclude the behaviour of the guilty nodes. Each watchdog in the neighbouring list broadcast the alert message and arrives at the conclusion. On affirmation, the nodes involve themselves in regenerating the cryptographic materials and distributing the same among the trusted nodes. The base station is notified of the illegitimate node.

In (S & S, 2017) cross layer approach is adopted. The paper tackles sinkhole attack. LEACH protocol is used in the work. Two assumptions are considered in the work. It is assumed that cluster heads cannot be compromised. The nodes are availed flexibility to vary their transmitting power. Rectangular clustering approach is adopted. The network is divided into rectangular clusters of equal area. The average location of nodes is calculated using Dijkstra's algorithm. The MAC layer sends link information to the network layer. The information is evaluated considering re-transmissions. Using the estimations an optimal routing scheme is provided. Considering Packet-delivery ratio sinkhole attack is evaluated. The work considers only retransmission to locate sinkhole attack.

The authors have proposed a different way to detect sinkhole attack in (Krontiris, Giannetsos, & Dimitriou, 2008). Two scenarios are considered in the work. Mintroute protocol (Rassam, Zainal, Maarof, & Al-Shaboti., 2012) is considered where the routing tree is built considering the link quality estimates. Packet error rate is considered. Periodically an update packet is transmitted to check the packet loss based on the number of packets received by the neighbouring nodes. The data of the same is updated in all the nodes with the respective sender node IDs. The nodes under sinkhole attack persuade the other legitimate nodes to change their route and choose the adversary as its next hop. Once the message is received by the legitimate node, the same checks the received message. If the node is not the one of the legitimate node in its list, it rejects the offer. Second scenario considered in the work is Multihop Link Quality Indicator Protocol (MultiHopLQI) (Gupta, Sharma, Marot, & Becker, 2010). The nodes calculate the link quality based on its own hardware. A beacon message is broadcasted by the nodes. The receiver uses its hardware to calculate LQI. Link quality indicator provides the cost of the corresponding link. The payload is the summation of cost of all links that make the given path. The nodes in this environment check the advertised path cost of the node and makes a comparison with the path cost

with its parent. The comparison resulting in positive outcome aids the node to change its parent. This approach aids in immediate detection of the illegitimate node. The parent-child link LQI is measured and ensured not to exceed 10.

An efficient intrusion detection algorithm is suggested in (Ngai, Liu, & Lyu.M.R, 2007). Two conditions are considered in the work. The network having single and multiple adversaries is discussed. The dropping of packets in multiple adversary environments is discussed in the work. The sensors dispatch the information to the base station using multiple redundant paths. Analyzing the outcome of the normal nodes is detected in their vicinity. The constructed tree is broken down into sub trees. The illegitimate node denying the packet transmission is detected. To deal with tampered or false messages a different approach is proposed in the work. A secret key is communicated along with message authentication code. The hop counts are calculated is made a comparison with number of edges from the given node to the current node. Identifying inconsistency in the counts the illegitimate node is detected.

Two approaches are suggested by the authors to tackle sinkhole attack in (Shafiei, Khonsari, Dera-khshi, & Mousavi, 2014). A centralized approach is adopted to detect suspicious regions in the network. A geostatistical model is utilized to do so. Distributed monitoring approach is adopted. The base station periodically samples the deployment area and collects the residual energy from sampled nodes. Along with the residual energy geostatistical data is also collected. This data is used to measure criticality of the sampled region. Based on the analysis report the base station takes appropriate action. A geostatistical frailty survival model is utilized to detect energy holes. The model aids in establishing the connection between before and after the occurrence of an event. Using distributed monitoring approach details of guilty node is learnt. The aggregate rate of the packets and the energy used to transmit the packet is calculated. The difference in energy against the threshold puts the monitored node into suspicion. The base station on confirmation takes appropriate action.

The authors in (Salehi, Razzaque, Naraei, & Farrokhtala, 2013) have suggested detecting sinkhole attack in the network. The work adopts a methodology to detect a single malicious node and multiple occurrences of the same at the later stage. The algorithm verifies data consistency to find the guilty nodes in the network. Using network flow information the malicious node is detected. A low-overhead algorithm is used to detect the attacked area. The identification algorithm is followed after detecting the malicious node residing group. The nodes identify themselves by providing the Ids of their own and the next-hop node. As flooding procedure is adopted, the most used hop is identified. Using the information, the attacker detected.

In (Tumrongwittayapak & Varakulsiripunth, 2009) the authors have suggested a lightweight and robust algorithm to detect sinkhole attack. The algorithm is based on received signal strength indicator (RSSI) readings. Extra monitor nodes are used to obtain good amount of readings. The distance between the transmitter and receiver is measured based on transmit power with effective propagation loss. Lognormal shadowing model is used to calculate the transmission power. Visual geographic map is calculated by using RSSI value. The monitoring nodes aid in the process. The base station broadcasts hello message to the network. The sensors use the predefined information in the routing table to locate the next hop. Based on the transmission the monitor nodes draw its conclusion based on the received message.

One-way hash chain is used to detect sinkhole attack in (Sharmila & Umamaheswari, 2011). The proposed work uses padding logic for MD5 extension. The message digest of 160 bits length is calculated. This message digest is attached to the original message. The single block of message is sent as input to secure hash algorithm and message digest algorithm. The digest obtained acts as the initial value for next block message. The message after passing through the malicious node is liable to get

modified. This is compared with the digest forwarded by the trustable node. The comparison result aids in locating the guilty node.

A non-cryptographic method was suggested by the authors in (Sheela, Kumar, & Mahadevan, 2011). The proposed work does not require any encryption or decryption mechanism. The mobile agents are used to accomplish the task. The agent is a program segment that aids in self controlling. They move from one end of the network to another transmitting data. The designed system aids the valid node from listening to the cheating information from compromised node. Two algorithms are proposed in the work. The mobile agent carries some dummy data inside. The alteration of dummy data confirms corruption. The least visited neighbour list is jolted. The updates are amended in the cache memory when the agent visits the node. Data routing algorithm is designed using data stored in the mobile agent. The algorithm aids in finding the maximum repeated hop with less weight.

In (Qi, Hong, Xiaohui, & Qiang, 2012) multihopLQI protocol is used. The protocol calculates the link quality and aids in amending the current parent. The system detects the sinkhole attack using two methods. In the first method the received BeaconMsg is checked to have ID of the neighbour. In the second method the path cost of parent/child is checked not to cross 10. The work suggests using encryption/decryption mechanism or creating a blacklist.

A novel intrusion detection system is suggested to detect sinkhole attack in (Dallas, Leckie, & Ramamohanarao, 2007). The proposed work considers guarding base station and the static nodes deployed in the network. Directed flood routing protocol is used in the proposed work. The base station broadcast the route advertisement to the sensors. The broadcast makes the sensors aware of the data collection point. The hop-count is updated in all the nodes. The methodology used aids in detecting the node under sinkhole attack. An alert is created which aids the respective nodes to take appropriate action on time.

A solution is suggested to detect sinkhole and wormhole attack in (Pirzada & McDonald, 2005). Dynamic Source routing protocol (DSR) routing is considered in the work. All the packets are affixed with DSR source route header. The list contains the complete route details the packet has to traverse to reach the destination. The source node broadcast the message with the destination address. The nodes listening to the broadcast, in-turn broadcast the same message affixing its address to the message. The broadcast is done in non-propagating manner to avoid repetition. The reply packet is generated by the respective transmitting node and broadcasted using the list obtained in the received packet. The work uses trust model approach. The model creates trust levels of the respective nodes in communication. The nodes monitor each other to measure accuracy and sincerity of its neighbouring nodes. An integrity check is done when a node receives a packet. The increment/decrement of the trust is based on the outcome of the analysis done by the monitor node.

The authors in (Le Fessant, Papadimitriou, Viana, Sengul, & Palomar, 2012) have suggested some measures to create resilience against the compromised nodes in the network. The proposed work is suggested to bring in solution for selective-forwarding and sinkhole attacks. Three tree-based routing protocols are studied in the proposed work. Hop distance is used to build the routing tree. Periodic routing aids in updating the routing topology regularly. Two resilient protocols are suggested in the work – RESIST-1 and RESIST-0. RESIST-1 protocol aids in preventing the illegitimate node from modifying its advertised distance. RESIST-0 does not allow manipulation of the advertisement at the cost of additional complexity.

A precise solution is suggested in (Stafrace & Antonopoulos, 2010) to detect sinkhole attack in short duration of time. To calculate precision ratio of true detection to the false ones are calculated. False detections are inclusive of false negatives and positives. The proposed work uses AODV protocol to establish route between two nodes.

A trust based intrusion detection system is proposed in (Ghugar, Pradhan, Bhoi, & Sahoo, 2019). Three layers are considered to calculate the trust value. At the physical layer denial of service attack is considered. The nodes are considered to accept malicious packets along with the expected ones. The proposed system assumes that the number of packets generated by the malicious node is always greater than that of the normal node. A pseudo random number uniform distribution pattern is analysed. To detect the malicious activity, energy consumed and number of messages metrics is obtained from the monitoring nodes. The second layer into consideration in the work is MAC layer. Back-off manipulation attack is considered in the MAC layer. To detect malicious node the back-off time parameter and number of successful message transmission parameter are considered. Network layer is the third layer considered in the proposed work. The malicious node in the proposed work is assumed to broadcast fake messages w.r.t hop count. Route reply packet is used to perform so. To detect the malicious activity hop count metrics is utilised.

The Negative selection algorithm is used in (Zhang & Xiao, 2019). Two kinds of infrastructure are used – flat infrastructure and hierarchical infrastructure. The intrusion detection system is used for the hierarchical model. The cluster head communicates with the base station. The nodes deployed are divided into three layers- application layer, immune layer and network layer. The cluster head commences with the immune layer. This layer is responsible to monitor the transmission flow in the cluster members and neighbouring cluster heads. The work uses variable-radius detectors. The negative selection algorithm analyses the distribution. Real-valued spaces are used to find the subspaces. The detector is activated based on the algorithm search. A mature detector is located if it crosses the tolerance.

PROPOSED WORK

Notations Used in the Study

The table 1 contains the description of the notations used in the proposed study.

Table 1. List of notations used in the study

Notations	Description
N	Network under study
N_i	i th node in the network
r	Assumed transmission range to receive communication
Ack	Acknowledgement message
Hello	Hello message
CH_i	Cluster head of i th cluster
U_{id}	Unique identification of the node
BS	Base station
K_i	Public key
S_{bs}	Signal used by the base station
H_i	Hash code
T_i	Sensed data to be transmitted

Assumptions Made in the Study

The following assumptions are made in the proposed work:

- The network is assumed to be free from any kind of attack till the nodes configure and commences the communication with each other.
- The adversary is capable of introducing sinkhole attack into the network. The nodes under this kind of attack will advertise itself as the most favourable path to the base station. After gaining trust of the legitimate nodes, they are capable of launching different kinds of attacks into the network.
- The base station is assumed to be most trustable node in the network. All the other nodes of the network are liable to get compromised.

Deployment of Nodes in the Network

The base station embeds the keying materials into the nodes prior to the deployment. The nodes in the network are deployed randomly. The nodes self-configure and broadcast Hello message. In notation (1) node N_i is broadcasting Hello message to the network N .

$$N_i \rightarrow \text{Hello} : N. \quad (1)$$

The nodes within the transmission range r will be able to receive the transmitted message. They respond with the acknowledgement message. In notation (2) node N_j is acknowledges with the Ack message to node N_i .

$$N_j \rightarrow \text{Ack} : N_i. \quad (2)$$

These nodes form the cluster. A cluster head is chosen randomly in the first round. The head selection is rotated to other nodes in the network to increase the lifespan of the nodes. The cluster head is chosen based on the residual energy in them.

Finding the Route to the Base Station

The base station broadcasts public key to the network. In the equation (3) the base station BS is broadcasting public key K_i to the network N .

$$BS \rightarrow K_i : N. \quad (3)$$

The base station broadcasts Hello message along with the public key to the nearest nodes using a particular signal. The signal is the same used by the sensors of the static nodes to communicate with each other. In equation (4) the base station is broadcasting Hello message and public key K_i to the network using the signal strength S_{bs} .

$$BS \rightarrow S_{bs} (Hello, K_i) : N. \quad (4)$$

The nodes which are able to listen to the signal respond with the acknowledgement message. The nodes encrypt the node identification using the public key and transmit the same to the base station. In the equation (5) the base station BS is broadcasting Hello message and unique identification encrypted using public key K_i to the base station BS.

$$N_i \rightarrow (Ack : K_i (U_{id})) : BS. \quad (5)$$

The base station after receiving the message from the nodes decrypt using the private key and identify the message for its legitimacy. The authenticated nodes broadcast the Hello message to other nodes in the network with the same signal strength. It receives the acknowledgement message along with encrypted node identification message. This is forwarded by the respective nodes to the base station. The base station evaluates them for their legitimacy and broadcasts if it finds any malicious nodes in the network.

In this way all the nodes in the network are authenticated and their location is traced. This procedure is repeated at certain intervals of time and the data is updated. All the nodes maintain the list of legitimate/illegitimate nodes and the path is updated.

Attaching the MAC Message to the Transmitted Message

A hash code is generated using the node identification. Both the sensed message and the hash code are encrypted using the public key. In equation (6) the message T_i and generated hash code H_i is encrypted using the public key K_i and transmitted to the next authenticated hop N_j .

$$N_i \rightarrow K_i (T_i || H_i) : N_j. \quad (6)$$

To ensure security in the network, the hash code is changed for every session. The receiving node forwards the message to the base station. The base station on receiving the message decrypts the message using its private key. The hash code is cross-verified for its legitimacy. The base station ensures that it transmits different public key to the network for every session. The measure increases security of the data in the network. The methodology implements forward secrecy.

Analysis of the Work

The work is suggested to minimize sinkhole attack in the network. The base station authenticates the nodes of the network by evaluating the transmitted encrypted node identification. The signal strength broadcasted gauges the distance between each other. The suggested work aids the node to find appropriate path for transmission. The compromised node can be detected in the following manner.

- *Assuming the cluster head is compromised* – The cluster heads transmits the message to the authenticated nodes of the network. If the head is compromised it will either falter while authenticating or while transmitting the message to the next available hop. The base station will be able to find the malicious node after receiving the message. On affirmation of the illegitimacy, the nodes

will be notified for its activity. The nodes make an entry of the guilty node and choose another node as its cluster head.

- *Assuming the cluster member is compromised* – The cluster members sense the environment and transmit the data by encrypting them using public key. The cluster members encrypted hash code is also attached to the transmitted message. This is evaluated by the base station. The hash code has to change with every session and has to sync with the node identification. The compromised node will not be able to do so and hence the malicious activity can be detected. After receiving notification from the base station, the malicious node is isolated from the cluster.

Simulated Work

The work is simulated using NS2. Various parameters are used in the proposed study. The dimension of the network considered is 500m *500m. The nodes are deployed randomly. 100 nodes are deployed in the network forming 12 clusters. The same is represented in the Table 2.

Table 2. List of parameters used in the proposed work

<i>Parameters</i>	<i>Description</i>
Dimension	500m*500 m
Number of static nodes deployed in the network	100
Distribution of nodes	Random
Number of clusters	12
Length of sensed message	840 bits
Length of the hash code generated	84 bits
Length of private key generated by base station	240 bits
Length of public key generated by the base station	240 bits
Time interval	60s

Energy Consumption

Energy (Fabri.F, Buratti.C, & Verdone.R, 2008) is one of the limited resources in sensors. Hence consuming the same becomes essential. The following methodologies are utilized to increase lifespan of the nodes in the network-

- Multi-hop transmission is adopted- The cluster head transmit their packets to the next available hop and hence large amount of energy is conserved.
- Cluster based transmission (Xiangning, 2007) is adopted- The proposed work adopts cluster based routing. The nodes able to hear each other are grouped together. The cluster members transmit their packets to the group head. The group head transmits the aggregated packets to the next available hop.
- Authentication (Abraham & Ramanatha, 2006) (Butun & Sankar, 2011) is performed for every certain time interval. This is the preliminary stage where the nodes are able to identify each other before the transmission commences. Illegitimate nodes are traced at an earlier stage. The nodes

undergo authentication for certain interval of time and hence the malicious nodes can be detected and isolated.

The proposed work is compared to (Ghugar, Pradhan, Bhoi, & Sahoo, 2019). The base station in the proposed work broadcasts the public key which is later used by the nodes to-

- Encrypt hash code
- Encrypt transmitted message

The base station decrypts the encrypted message using its private key. As only the base station will have the decryption key, the communication would remain secure. The base station repeats the broadcasting process for every session. Hence security for the transmitted data is enhanced. Increased security keeps away the illegitimate nodes and reduces unnecessary use of resources.

A trust based intrusion detection system is proposed in (Ghugar, Pradhan, Bhoi, & Sahoo, 2019). Three layers are considered to calculate the trust value. At the physical layer denial of service attack is considered. The nodes are considered to accept malicious packets along with the expected ones. The proposed system assumes that the number of packets generated by the malicious node is always greater than that of the normal node. A pseudo random number uniform distribution pattern is analysed. To detect the malicious activity, energy consumed and number of messages metrics is obtained from the monitoring nodes. The second layer into consideration in the work is MAC layer. Back-off manipulation attack is considered in the MAC layer. To detect malicious node the back-off time parameter and number of successful message transmission parameter are considered. Network layer is the third layer

Figure 1. Comparison of energy consumption in the network

considered in the proposed work. The malicious node in the proposed work is assumed to broadcast fake messages w.r.t hop count. Route reply packet is used to perform so. To detect the malicious activity hop count metrics is utilised. Taking entire network into consideration, the total trust value to be calculated is

Trust value = number of nodes * number of transmissions * length of the message * number of clusters in the network.

Energy consumption at receiving end = (number of nodes * energy consumed by receiving nodes)

Energy consumed at transmitting end = (number of nodes * number of transmissions * energy consumed for transmission)

Total energy consumed = (Energy consumption at receiving end + Energy consumed at transmitting end) * number of clusters

In (Ghugar, Pradhan, Bhoi, & Sahoo, 2019) three layers – physical layer attack, MAC layer attack and network layer attack is considered. The energy consumption to make the nodes secure against these attacks is higher by 18.18% compared to the proposed work. The same is represented in the fig 1.

Security Against Sinkhole Attack

The work proposed by the authors in (S & S, 2017) uses Dijkstra's algorithm to find the location of the nodes. It suffixes the MAC message to authenticate itself. The proposed study is an improvement over (S & S, 2017). Two measures are adopted to safeguard the data against the Sinkhole attack in the proposed work-

- The proposed work uses broadcasting procedure where the base station authenticates the nodes nearer to itself. The legitimate nodes authenticate other nodes of the network within the signal range. Hence all the nodes get authenticated and this procedure is performed for every session. The node provides their authentication by transmitting the node identification in the encrypted form. As the base station has the private key, it decrypts the received message to authenticate them.
- The nodes also suffix the generated and encrypted hash code to the transmitted message. The methodology brings in better security to the transmitted data by enhancing security by 22% with comparison to the work (S & S, 2017). The graphical representation for the same is provided in figure 2.

Figure 2. Comparison of security against sinkhole attack

FUTURE RESEARCH DIRECTIONS

The proposed work uses broadcasting procedure where the base station authenticates the nodes nearer to itself. The legitimate nodes authenticate other nodes of the network within the signal range. Hence all the nodes get authenticated and this procedure is performed for every session. The node provides their authentication by transmitting the node identification in the encrypted form.

The base station broadcasts the public key which is later used by the nodes to encrypt hash code and encrypt transmitted message. The base station decrypts the encrypted message using its private key. As only the base station will have the decryption key, the communication would remain secure. The base station repeats the broadcasting process for every session. Hence security for the transmitted data is enhanced. Increased security keeps away the illegitimate nodes and reduces unnecessary use of resources. To enhance the proposed work –

- The receiving nodes also consume energy to accept the transmitted message. As the number of transmission by the base station is increased to bring in security to the network increases, the nodes also consumes lot of energy. Reducing the energy consumption can be considered in future work.

CONCLUSION

Wireless sensor network are devices used in many applications with varying utilization. These unsupervised devices require adopting some strong mechanism to provide secure communication to data. Sinkhole attack is one such attack where the adversary advertises itself as one of the best hops available to reach the base station. The legitimate nodes unknowingly will share the key credentials and other information.

The proposed work is suggested to bring in better security to the network by detecting the malicious node at an early stage. The base station uses the signal strength to draw in the acknowledgement from the nodes that fall into the inner circle. Using the signal strength aids in measuring distance between the nodes. The legitimate nodes in-turn authenticates the respective nodes using the same signal strength. The procedure aids in authenticating the entire network. The base station broadcasts public key to the network for every session. This key is used to encrypt the transmitted data, encrypting the node identification during authentication procedure and encrypting the hash code. The hash code is changed for every session to enhance security in the network. As the private key only resides with the base station, only the same will be able to decrypt the message. The procedure aids in increasing forward secrecy. It enhances security towards sinkhole attack by 22% and minimizes energy consumption by 18.18% with a comparison to previous work. The methodology increases confidentiality and integrity to data.

KEY TERMS AND DEFINITIONS

Energy Consumption: The amount of energy consumed using different methodologies in the proposed work

Hash Code Generation: A hashing algorithm is used to generate the hash code (an integer value) accepting the identification of the nodes as the input.

Public Key: Two keys are generated in public key cryptography. The public key is broadcasted by the source node to the nodes of the network. The nodes use the same to encrypt the messages before transmission. The source decrypts the received message using the private key.

Security Methodology: The measures used to bring in security to the nodes and the transmitted data in the network.

Signal Strength: The nodes based on their capacity transmit the packets with certain signal strength.

Sinkhole Attack: This is a kind of attack where the malicious nodes broadcast bogus messages to the nodes within the vicinity to bring them into confidence. The legitimate nodes transmit their packets to the malicious nodes which are later used to launch different kinds of attacks.

Wireless Sensor Network: Wireless sensor network (WSN) refers to a group of spatially dispersed and dedicated sensors deployed to monitor/track any object of interest.

TDSJ-IoT: Trivial Data Transmission to Sustain Energy From Reactive Jamming Attack in IoT

INTRODUCTION

Internet-of-things (Stankovic, 2014) is a combination of sensor technology with Radio Frequency Identification Device (RFID) (Jia, 2012) (Fan, Gong, Du, Li, & Yang, 2015), Geological Information System (GIS) (Liu, 2014) (Lopez, Lopez, Prieto, & Quinde, 2017) and Global positioning system (GPS) (Kumar, 2017) (Mala, Thushara, & Subbiah, 2017) (Jisha, Jyothindranath, & Kumary, 2017). The devices communicate with each other using integrated technology. The integration has aided to improve the quality of one's life minimizing human efforts. The technology consisting of a variety of devices aims to think, hear which aid in their doings and share information with each other. Four components are used to do the same. Sensing, heterogeneous access, information processing, applications, and services come together to bring the technology into play. The devices using the underlying technology turn the doings to become smarter. The applications include transportation (Melis, 2016) (Masek, et al., 2016), agriculture (Mat, 2016) (Popović, 2017), industry automation (Shrouf, 2014), emergency response (Yang, 2013) (Rathore, 2016) and healthcare (Muhammad, 2017) (Mano, 2016). Security (Andrea, 2015) and privacy components can be added to make the technology better.

Security in these devices is one of the prior issues to be considered as these devices will not be under continuous supervision. Hence the devices are liable to different kinds of attacks. Jamming attack (Alaba, 2017) (Kasinathan, 2013) is one such attack where the packets dispatched to the destination is hindered to reach the same. This leads to loss of packets and rarely the packets may reach the destination improperly. Many kinds of jammers are available. This includes basic jammers – reactive jammers, constant jammers, deceptive jammers, and random jammers. The second category of jammers namely intelligent jammers is of two kinds - statistical jammers and protocol-aware jammers. Each jammer has different characteristics and is active on different layers of the network. The descriptions of them are narrated in section 2.

The proposed work minimizes reactive jamming attack (Grover, 2014) (Babar, 2013) in the network. The work adopts some precautions to be taken to identify the adversaries before in hand. The methodology used will be able to detect the intruder earlier in the stage. Three kinds of precautions are taken in the proposed work. First, the devices are to sense the channel before commencing communication with any other device. They will be in continuous vigilance monitoring their surroundings. Second, to find the appropriate route, the device broadcasts sample bits addressing the receiving device. The reactive adversary sensing the packets are liable to transmit its packets. Hence the packets of the legitimate source will not reach the desired destination or will take a lot of time to reach its destination. The receiver affixes the time and path from which the packet it has received. Using this information the

DOI: 10.4018/978-1-7998-3479-3.ch038

further communication path is set. As the device is continuously sensing the channel it will be able to figure out jammers to some extent. Third, every device dispatching the packets will be equipped with device-id. Using the device-id, a hash code is derived which uniquely identifies the device. The hash code is prefixed to the transmitted packets. The receivers analyze the prefixed code along with signal strength and continuous with the communication if found legitimate. Using these steps reliability to the communication is increased by 4%, the effectiveness is increased by 7.6% and energy is minimized by 6.3% compared with the previous work.

The work is divided into eight sections. The introduction to the work is provided in section 1. Different kinds of jamming attacks are detailed in section 2 and Literature survey is explained in section 3. Section 4 contains the detailing of the proposed work. The details of the simulation are done in NS2 is provided in section 5 and the analysis of the same is provided in section 6. Section 7 details the future work to be taken. The work is concluded in section 8.

JAMMING ATTACKS

Different kinds of jamming attacks are available. Two kinds of jammers are available. They are basic and intelligent jammers (Hamza, 2016) (Noubir, 97-108). The basic jammers are into dispatching the packets are different intervals of time continuously or discreetly. Basic jammers are of four kinds- namely constant jammers, random jammers, deceptive jammers, and reactive jammers. The intelligent jammers are designed to understand the underlying technology and implement jamming to hinder the transmission. Intelligent jammers are of two kinds namely statistical jammer and protocol-aware jammer. Their characteristics are detailed in Table 1.

Table 1. Characteristics of different kinds of Jammers

Type of jammers		Characteristics
Basic jammers	Constant jammers (Han, 2018)	· This kind of jammer is effective on physical layer. · The jammer transmits continuous random bits without following any MAC label.
	Deceptive jammers (Lee, 2014)	· This kind of jammer is effective in MAC layer · The adversary continuously inject regular packets without any interval between packet transmission
	Random jammers (Wei, 2014) (Sanguanpong, 2018)	· The jammers toggle between sleep and jamming state. · This kind of jammer is effective in MAC layer
	Reactive jammers (Fadele, 2018) (Sciancalepore, 2018)	· This kind of jammer is effective in MAC layer · They emit radio signal on detecting any activity in the channel · These jammers keep the channel busy
Intelligent jammers	Statistical jammer (Ren, 2013)	· This kind of jammers are effective in physical layer · Observes the packet inter-arrival distribution and regulates itself to the traffic disrupting communication of the network
	Protocol-aware jammer (Sufyan, 2013) (Toledo, 2008)	· These kinds of jammers are effective in MAC layer. · It Keeps itself updated with the operating rules and deprives the legitimate nodes using its database.

BACKGROUND

Internet-of-things is used to link two devices and enables communication among them. As these devices are not under continuous supervision they are liable to different kinds of attacks. The proposed work aids in minimizing jamming attack in the network. The reactive jamming attack is considered in the work. Radio interference attacks are responsible to cause serious injury in the network. The following section provides a detailed study of the jamming attacks proposed by various authors.

In (Xu, 2005) jamming attacks are analyzed in wireless networks. The work is evaluated in two stages. In the first stage, the problems that crop up when radio interference attack is encountered is scrutinized. In the second stage, critical issues of diagnosing the presence of the attack are dissected. Four kinds of jamming attacks are introduced into the network and the effect on the wireless network, their ability to receive and send messages is evaluated. The work is analyzed considering the signal strength and carrier sensing time. The proposed work used Mica2 as the platform to conduct the respective experiments. The MAC protocol waits for the idle slot for a random amount of time to transmit the packets. The four kinds of jammer – constant jammer, reactive jammer, random jammer, and deceptive jammer were evaluated. Berkeley notes that employ ChipCon CC1000 RF transceiver and TinyOS operating system were used to implement and evaluate the working of the study under the four kinds of jamming attacks. The channels were disabled to sense the packets and the backoff operations to bypass MAC protocol to introduce the attacks in the network. The study will not be able to analyze the difference between the congested packet and jamming attack.

Reactive jamming is evaluated in (Wilhelm, 2011). An IEEE 802.15.4 network is used to examine the proposed work. The causes of loss at the physical layer are identified and a solution is provided to tackle reactive jamming attack. To detect the attack detection of jamming, scheduling and initialization of jamming and jamming burst to destroy the packet is calculated against the minimal time required for jamming. The proposed work concluded that minimal jamming duration is $26\mu\text{s}$, jamming initialization time was set to $15\mu\text{s}$ and the detector added a delay of less than $4\mu\text{s}$. The accounted data is used to check the same against USRP2-based reactive jamming prototype.

In (Raya, 2007) jamming attack was experimented on vehicular networks. Analyzing the threat analysis appropriate security architecture was devised. Digital signatures were used to protect the message legacy from the adversaries. The work adopts to use set of public/private keys pairs to digitally sign the messages and authenticate itself to the receivers. To tackle revocation of certificates a set of revocation protocols Revocation Protocol of the Tamper-proof Device (RTPD), Revocation protocol using Compressed Certificate Revocation list (RCCRL) and Distributed Revocation Protocol (DRP) are used. Using the protocol the malicious behavior can be detected.

A game-theoretic analysis is used to evade the attack of an aerial jammer on a communication channel (Bhattacharya, 2010). The kinematic model of the nodes is considered. To obtain optimal strategies, saddle point strategies are used. This is a zero-sum game which has a set of strategies for the players are used to arrive at the equations governing the saddle point strategies. In (Brown, James, & Sethi, 2006) the authors have considered an attacker disrupting an encrypted victim wireless adhoc network using jamming practice. Jamming at the Transport/network layer is considered in the work. The analysis revealed that TCP-SYN and TCP-SYN-ACK packets prevent TCP connection. ARP-REQUEST and ARQ-RESPONSE will prevent IP from associating IP and MAC address. Sensing is considered to be both online and offline. Online sensing packets are identified as they are received by the destination. Offline sensing is used to categorize the packets received in the history doings. The spread spectrum

proposed in the work provides a jamming immunity proportional to the spreading factor. The authors used Linux laptops running AODV-UU protocol while conducting testbed.

The authors in (Li M. K., 2007) have provided a solution for single-channel wireless sensor networks. The sophisticated jammer in the work controls the probability of the jamming and transmission range aims to corrupt the communication links in the network. The monitoring node is responsible to monitor the doings of the other nodes in the network. The supervising node conveys the alert message to the respective. The monitoring node is responsible to estimate the percentage of incurred collisions and draw out the outcome of optimal detection test. The network computes channel access probability to aid in minimizing jamming detection and reporting time. The study focuses to understand the problems regarding the structure, identifying the tradeoffs and capturing the impact of different parameters on its performance. The study is made to bring in a strategy which aims to handle the situation in case of knowledge-based/without a knowledge-based scenario. The network and monitor node without the knowledge uses the formulation and resolving optimization problems.

Path-based Dos attack is dealt in (Deng, 2005). The wireless sensor network will undergo serious damage. The intruder either injects replays the packets into the network or spurious packets. The adversary aims to block the path by introducing jamming packets and initiating the base station to re-boot the OHC (a sequence of numbers) for all the nodes on the path. Two methodologies are adapted aiding to minimize jamming and forgo the above scenario. OHC proactive bootstrapping employs to bootstrap the nodes near the jamming path and refreshing the OHC sequence. Another approach is known as lazy OHC bootstrapping where the addition of a new node to the network does not commence bootstrapping but still maintains resilience to stop Dos attack.

In (Hamieh, 2009) the authors have designed a solution for jamming attacks in mobile Adhoc networks. The authors have used a scenario where the jammer gets itself into its doings when valid radioactivity is signaled. The adversary moves to sleep state when it is not jamming the signals. To find the solution to this kind of attack, dependence among the periods of error and correct reception times are analyzed. The correlation coefficient is used to compute the same. The coefficient is the statistical measure of the relation between two random variables. To evaluate the jammer, error probability and correlation coefficient is measured.

In (Sampath, Dai, Zheng, & Zhao, 2007) 802.11 networks are considered. A detailed study on Single-channel jamming and multi-channel jamming attacks is done in this work. In the case of single-channel jamming attack, the adversary transmits high power signals on the channel. The impact of jamming depends on the size of the packets, length of inter-jamming interval and size of jamming packets. The adversary is observed to transmit 50-byte size packets to disrupt the data link. According to the experiment conducted in the work 100% —40% of packets suffer from degradation. Considering the second scenario, multiple radio devices are used to cause multi-channel jamming attacks. The impact can cause 5-100ms switching delay.

The solution to Spoofing-jamming attack in wireless smart grid network is detailed in (Gai, 2017). The work considers both jamming and spoofing to intrude in the communication. The frequencies used to transmit jamming packets vary with time. Spectrum adversarial occupations are used to maximize the attack effect. The study uses dynamic programming to solve power distribution optimal problem. The study is evaluated using the simulator MAS-SIM.

PROPOSED STUDY

Assumptions Made in the Study

- The base station is considered to be the most reliable resource.
- The network is vulnerable to jamming attack. The reactive jammer introduces the packets which it receives the signal from the channel when the channel transmits any of the packets.

Working of the Proposed Work

In (Xu, 2005) the author has suggested examining the signal strength and carrier sensing time. Analyzing the signal strength aids the receiver to accept/reject a packet from receiving. The adversary will usually aim to transmit the packets with high signal strength and hence scrutinizing the strength refrain from accepting the packets from the adversaries. Carrier sensing time aids in providing the picture of the occupancy of the channel. If the channel is constantly occupied the source will use another path to communicate its packets. The work proves to tackle jamming attack at its best in case of constant jamming. But the adversary introducing reactive jamming attack transmits its packets only when there is a packet movement in the channel. Hence using the methodology some initial packets can get lost and the source may have to retransmit the same.

The proposed work is suggested to improve the work suggested in (Xu, 2005). The work is put forward to tackle the reactive jamming attack. In this kind of attack, the adversary transmits the packets when it senses any transmission in the channel. The proposed work operates using the following steps-

- The devices are habituated to sense the channel before commencing communication with any other device. They are in continuous vigilance monitoring their surroundings.
- To find the appropriate route, the device broadcasts sample bits addressing the receiving device. The reactive adversary sensing the packets are liable to transmit its packets. Hence the packets of the legitimate source will not reach the desired destination or will take a lot of time to reach its destination. The receiver affixes the time and path from which the packet it has received. Using this information the further communication path is set. As the device is continuously sensing the channel it will be able to figure out jammers to some extent.
- Every device dispatching the packets will be equipped with device-id. Using the device-id, a hash code (Riedel, 2010) is derived which uniquely identifies the device. The hash code is prefixed to the transmitted packets. The receivers analyze the prefixed code along with signal strength and continuous with the communication if found legitimate.

SIMULATION OF THE WORK

The proposed work considers three steps to tackle reactive jamming attack. The devices are under continuous vigilance. They try to be completely aware of their surroundings by listening to the channel before any transmission. This procedure keeps them aware of the jamming attack in its vicinity. Secondly, they transmit sample data to probe the adversary into its act. Hence the methodology aids in locating the jammer position and keeps its packets away from them. To enhance reliability to the transmitted packets, the devices prefix hash code generated by the device-id.

The work is simulated using NS2. MICA2 motes (Narayanan, Sarath, & Vineeth, 2016) are considered in the simulation work. 4 motes are installed in the environment of area 200m * 200m. The sample bits are of 4 bits in length. The hash code is 8 bits in length and the transmitted data is of 64 bits in length. The work is simulated for the 60s. Table 2 depicts the details of the simulation.

Table 2. Depiction of simulation parameters used in the study

Parameters used	Description
Simulation area	200m * 200m
Number of motes installed	4
Number of jammers	1
Length of sample bits	4
Length of hash code	8 bits
Length of transmitted bits	64 bits
Simulation time	60 s

ANALYSIS OF THE PROPOSED WORK

Energy Consumption

Energy (Al-Ali, Zualkernan, Rashid, Gupta, & Alikarar, 2017) (Chiu, Sun, Thompson, Nakayama, & Zhang, 2017) is one of the most important resources in these devices. The devices lose a certain amount of energy while receiving and accepting packets. Hence to curtail the energy consumption by avoiding retransmission and accepting legitimate packets the proposed work is suggested.

The proposed work aids in minimizing the energy consumption of the receiving device. Three steps are considered in the proposed work to minimize energy getting drained in the receiving node. The energy is curtailed as the devices become aware of their environment and can transmit their packets safely to their respective destination. The methodology restricts retransmission of the packets.

- The devices are into the practice of examining and sensing the channel before commencing any kind of transmission.
- An appropriate path is chosen to communicate with the other device by using the broadcasting mechanism.
- The packets are prefixed with the hash code of the respective device providing an identity of the packet origin.

The work suggested by (Xu, 2005) uses signal strength to analyze the packets. The adversaries are assumed to transmit the packets with high signal strength and hence only the packets with appropriate signal strength are accepted. As the network is dealing with reactive attacks, the adversary transmits its packets only when it senses packets in the channel. The suggestion provided by (Xu, 2005) would not be able to trace the adversary on time and hence will suffer from loss of some of its packets in the attack. This triggers the source to retransmit the packets to the destination. The proposed work will be able to detect the attack while it broadcast sample bits into its environment and sensing the channel. Hence

considerable numbers of packets are saved from the loss against jamming attack. This, in turn, consumes some amount of energy in these devices. Comparing the proposed work with (Xu, 2005) nearly 6.3% of energy is saved using three energy conservation steps. The same is depicted in Figure 1.

Figure 1. Depiction of energy consumption in TDSJ-IoT and (Xu, 2005)

Effectiveness of the Steps Considered in the Work

Carrier sensing time and signal strength are analyzed in (Xu, 2005) to transmit the packets into the channel during that duration of time. The work proves to work better with the constant jamming attack but will shortfall with the reactive jamming attack.

The proposed work analyses the channel in multiple ways which aid the devices to conserve some amount of energy and also tackles the attack on time. The work aids in monitoring the environment continuously to bring in better awareness of the vicinity to the devices. Using sample bits in transmission triggers the adversary and keeps the legitimate devices aware of their location. Prefixing the hash code to the transmitted packets enables to improve reliability to the transmission. Comparing the work suggested in (Xu, 2005) and the proposed work proves to be effective by 7.6%. Figure 2, provides the depiction of the comparison of the effectiveness of the proposed work and the work suggested in (Xu, 2005).

Figure 2. Graphical Representation of effectiveness of the algorithm against attacks

Reliability to the Transmitted Packets

In (Xu, 2005) the authors have suggest minimizing the jamming attack by using carrier sense time and signal strength. The proposed work adds another vital ingredient to the transmission. The packets received by the destination will provide more reliability (Li L. J., 2012) (LI, 2012) (Ahmad, 2014). The hash code is generated using the device-id and this code becomes the identification of the device and its transmitted packets. Comparing the work with (Xu, 2005) the proposed work provides 4% more reliability to the transmitted packets. Figure 3 provides the graphical representation of the comparison of the proposed work with (Xu, 2005) concerning the reliability of the transmitted packets by the source to the respective destination.

Figure 3. Depiction of reliability of packet transmission in reactive jamming prone network

FUTURE WORK

The proposed work aids in minimizing the reactive jamming attack in the environment. The challenge is how it secures its packets from the jammer. It follows three steps to do the same. It will be under continuous vigilance monitoring its vicinity. This methodology aids in making the devices aware of their environment. The devices trigger the adversary by broadcasting sample bits in the network. This enables the devices to locate the jammers and keep their packets away from them. To increase reliability to the transmitted packets it prefixes hash code to the packets before transmission. To make the methodology even better the following points are to be considered-

Energy Consumption

As the devices are into continuous awareness, the energy consumption is relatively high comparative to devices which move into a sleep state. Hence better methodologies have to be devised to adopt some duration of sleep to these devices. The devices broadcast sample bits every time it has to initiate communication. This methodology also consumes a lot of energy and has to be curtailed.

Change of Hash Code

The hash code derived from the device-id and prefixed to the transmitted packets remains the same throughout. Hence to keep the transmission safer better methodology has to be adopted to change the hash code with different sessions.

CONCLUSION

Internet-of-things is a new technology which enables many devices to communicate with each other. The devices in communication may belong to the same category sharing the same platform or may belong to different categories. The technology aids in bridging the gap between the categories and building a common platform where the devices will be able to communicate with each other securely. As the devices are not under supervision, they are liable to different kinds of attacks. This paper tackles reactive attacks in the network. Energy and timeliness are some of the prior issues to be addressed in this network.

The proposed work uses three effective steps to minimize the packets getting lost or destroyed in the jamming attack. The algorithm is into sensing the channel which keeps the devices updated with the surrounding environment it is residing at that instant of time. The second suggestion provided by the proposed work is to broadcast bits of sample data. Utilizing this methodology the adversaries are triggered to transmit their jamming packets to hinder transmission. Hence the adopted methodology aims to identify the location of the jammer. The proposed work using the methodology will use a reliable path to transmit its packets to the destination. To make the transmission more reliable, a hash code generated using the unique identification of the device. This, in turn, enhances reliability to the packets delivered. The proposed work proves to be more effective by 7.6% than the previous work and also conserves 6.3% of energy. Reliability of the transmission of packets is increased by 4%.

KEY TERMS AND DEFINITIONS

Hash Code: Hash code is a numeric value generated that helps in identifying the object.

Internet of Things: The Internet of Things shortly known as IoT is a system of interrelated computing devices. The objects of interest are provisioned with unique identifications. This facility aids in transfer data over a network without human-to-computer interaction.

Reactive Jamming Attack: This kind of jammer is effective in MAC layer. The adversary emits radio signal on detecting any activity in the channel. These jammers keep the channel busy.

INTRODUCTION

Data and Knowledge are at the level of all organizations. Due to the amount of data generated, companies require different analyzes, supporting data-driven decision making (Nimmy et al., 2017). Well-organized management of data and knowledge are the key to the success science related data and then the almost of any enterprise.

The issue of data and knowledge management (Ermine and al., 1996) has been defined as the implementation of a management system that allows all components of the company (Brunet et al., 1994) to use and enrich knowledge and to consider this heritage of knowledge as the same subject of the information system of the company (Ermine, 2000). As a result, the technological revolution has brought about a change in the way information/data is collected (Kamal et al., 2017) and treated and so the implication of the *Components*.

Any conventional design of complex software systems always starts with the identification of the system in parts (subsystems, blocks, class, etc.) where the idea and the concept of the components come from, i.e. the decomposition of the system is to bring out the parts which are interested. It is no coincidence that the notion of component gives a great interest in the development of complex systems.

Certainly, the importance and usefulness of components in scientific research are not new topics, especially in the reuse of components. Formerly, this work focuses on the complete definition of component-based information systems approach design.

The idea of component-based development is introduced by defining the concept and providing its management. The approach primarily seeks to explain and analyze and manage the variety of data and information exchanged in a company. This method is useful for a global vision of the company's system, using phases and steps designed tailored to the needs. This represents a lot of "Components" not yet developed in implementation.

The difficulty is to design the components and the services most relevant to the goals. Design requires a method for modeling that involves creating a virtual representation in such a way as to bring out the goals interested in and build upon.

In fact, there is no standard for modeling a component-based system, so it is necessary to try to propose a component identification approach, and an approach to illustrate the management of a software system.

The objectives of this chapter the contribution of a new solution of the method based on software components, and a communication management approach between these identified software components mediators between the components and the information system. Hence, the idea that software systems can be developed by components intended to provide specific services such as combining, managing, connecting and communicating between system units.

This paper is organized in separate paragraphs and sections, distributed as follows:

- Section 2: Provides definitions incorporating general discussions on Data Management and Component Development, presents the state of the art (literature review).
- Section 3: formalizes the model of the proposed approaches.
- Section 4: presents the different elements of the technology served in this area.
- Conclusion: The paper ends with a conclusion.

BACKGROUND (SECTION 2)

Commonly, a system processes the data with a set of actions from a huge store of information and then invoking the input / output functions. A computer system has the function, in a very general way, of processing information. One of the first difficulties is to define the notion of information and in particular to delimit it in relation to related notions such as data and knowledge. Knowledge is used all the time and on many occasions, it refers to information. The difficulty of defining knowledge comes from its relationship to two concepts, data and information. Data are not organized in any way and provide no further information. As a result, data, information and knowledge are defined as follows:

The first concept to meet is the **data** which is a raw element not yet explained or guessed. The contextualization in an interpreted **data**, by creating one or more added values, generates **information** (Davenport & Prusak 2000).

Information systems are supported by processing systems that process only data and then the **data** is transformed into **information** when it is communicated to a human being capable of interpreting and deciding it (Bali et al. 2009).

The interpreted **information** is then transformed into contextualized **knowledge** and put in relation with existing **knowledge**.

Subsequently, **knowledge** comes and considers itself as **information** understood, that is to say, assimilated and used, which leads to an action (Davenport & Prusak 2000).

For **data** to become **information**, it is required to be contextualized, categorized. The **data** give the key to make the decisions and methods suitable for improvement (Kamal and al., 2016), supporting data-driven decision-making and management.

Design of meaning assigned to the data to make it an information and knowledge in a Micro-credit Agency does not extend credits for people over 60 years of age: the **data** 05-11-1956 generates the **information** that November 5, 1956 is a date of birth and 64 years is the **knowledge** that will alert and decide that his file will be rejected by the system.

In order for Knowledge Management (KM) to succeed, one needs a deep understanding of what constitutes knowledge.

More technologically, it is often treated as something can be codified and transmitted, similarly to information mainly involving information systems- knowledge. These two terms are often regarded as lower denominations of knowledge. However, even today, some KM systems are little more than information management systems using knowledge as a virtual synonym for information. Here, in summary the meeting of the three concepts:

- **Data** is the lowest point, an unstructured collection of facts and numbers;
- **Information** is the next level, and it is regarded as structured data;
- Finally **knowledge** is defined as “information about information”.

Figure 1. The relationship of the Management process: Data - Information- Knowledge

As a result of the amounts of data generated (Nimmy et al., 2017), companies require different analyzes, supporting data-driven decision-making, as enterprise resource planning (ERP) systems handle a huge amount of data, related to the actual execution of business processes and the work of (Pajić and al., 2016) is a detailed analysis of the concepts of approach centered on the artifact and describe its constructions by the meta-model and the capture of knowledge in data conversion. As a result, the technology revolution has brought a change in the way data are collected (Kamal et al., 2017).

In practice, information systems collect data by organizing them in easily accessible parts, but it is rare to directly define the status of implementation of dependencies between its different parts. The study of the treatment of multiple parts is generally simpler than the study of the overall treatment of a system, because each simpler component will be the subject of a separate study and simpler to study separately.

The principle of developing systems from the components is not new, it is even the object approach is based on the initial identification of the different elements of the system, then, modules and classes corresponding to each element. Irregularly, the term component is simply used as an equivalent for the object-oriented architecture.

The discussion in this paper is on some component-based approaches to object-oriented approaches, such as: UML Component (Cheesman, 2001) and Extraction of Component-Based Architecture from an Object-Oriented System (Sylvain et al., 2007), and others related to software-based engineering.

The approach, according to this work must start from the general, and go towards the particular, that is to say a guided by the functionalities of the system; the system is divided into components where each must perform a function (possibly several, if the component is decomposed into subcomponents with separate functions). These components make it possible to organize and cut the system into manageable and exchangeable pieces of software. So, what is a component and what is its task..

The idea of the component was first proposed in 1968 by (Douglas McIlroy, 1968). Before the software was built in one piece, and not assembled from components. With this lack of software component creation and modeling, software engineering has shifted the trend of application and software composition from separately developed software segments (Sosnin.P, 2016).

In computer science, a database can be component oriented, i.e. a database containing the set of data stored under a data management model, and programming via database management systems (Karaa et al., 2016).

The Component

The component is essentially characterized by two elements: its interfaces and its properties. An interface is a “use / provide” dependency relationship between the component and its environment. These

interfaces are characterized by the methods they define and by a direction of communication (provided, incoming / requested, outgoing) and can be defined as a specification of its access points via the port.

Between port and component, a connector connects these two or more connectable elements. It can be “Delegation” or “Assembly”. A delegation connector links a component to its internal subcomponents (Accord, 2002).

Typically, a component interface represents a set of functional and non-functional properties that are outside that component. The so-called functional properties describing the structure, the behavior and the functionalities of the component and the non-functional properties concerning the services used by the component that are not part of the application services (security, performance, etc.).

The Composite Component

The components are divided into two types, a primitive component and / or a composite component whose internal architecture is formed by several components, exposing its contents, named subcomponents, and are instantiated, interconnected and configured with the composite; represent a role played by a set of instances at runtime.

To avoid a common confusion of Component and Object, are they different things or not. Several temptations and directions have used the object to develop an optional component.

Literature Review

This part is dedicated to the introduction of component-based approaches related to object-oriented approaches.

• From Object Oriented to Component Oriented

The contribution of the components to the object is notably a greater modularity thanks to the encapsulation of the data and the explicit coupling of the dependencies required and provided. The classical approaches designate the notion object by the definition and the assembly of the element objects grouped the data and the treatments of these data.

Irregularly, the term component is simply used as an equivalent for the object-oriented architecture. Objects have a unique and inseparable class identity that encapsulates state, structure, and behavior. These classes are used to create a copy of a class named object (an instance of the class), and provide the implementation of the object behavior. As for the component, it breaks down into an outer part for the interfaces and another part /of the implementation. It is a storage unit to which is associated an implementation unit, allowing the description of the internal operation. In fact, a component can be implemented by a single class or by multiple classes, often hidden in the implementation and sometimes only available in binary form. The software components agree with the standards defined by a component model, they can come in different forms: class, specification, documentation, source code, class hierarchy, interface, etc.

a. UML Component (2001)

J.Cheesman and J.Daniels have proposed the UML Component method (Cheesman, 2001), for the design, development Objects, inspired by several methods, such as Catalysis (D’souza and al., 1998)

and RUP (Kruchten, 1998). UML Components, as the name implies, applies UML in the component architecture, to specify the components, their interactions, i.e. focuses on component specification by enriching UML notation with stereotypes to designate the specification of system models and divide these models into components.

Throughout, the emphasis is placed on the specification of the external characteristics of the components and their interdependencies, rather than on the internal activity. The study of the interactions between components is defined by the interfaces and therefore by calls of methods and services between components.

The proposed method is limited to the design level. Indeed, it does not explain how to interpret the specification of the component, in the implementation, or how to check the specifications at the compilation level.

b. Extraction d'Architecture à Base de Composants d'un Système Orienté Objet, 2007

Sylvain Chardigny, Abdelhak Seriai, Mourad Oussalah and Dalila Tamzalit (Sylvain and al., 2007) have developed an approach to extract a component-based architecture for the implementation of an existing object-oriented system. The primary idea of this approach is to propose a semi-automated process of identifying the components of a system based on their semantic and structural characteristics.

Extracting architecture is the reverse process of its design. Instead of using the architect's knowledge to create architecture and implement it, the extraction process uses its knowledge to obtain an abstraction of the system from its implementation.

c. Identifying a Component-Based Architecture in an Object-Oriented Application Using Dynamic Analysis (2011)

Systems with large numbers of elements, describes a complexity difficult to understand and maintain. The component paradigm provides a good representation of high-level complex systems, and can be used as "projection" of object-oriented systems.

Therefore, the goal of this work (Allier and al., 2011) is to propose a semi-automatic method to identify a component-based architecture in an object-oriented application.

The method should help in understanding the original application, as well as simplifying the projection of the application into a concrete component model.

The identification of a component-based architecture is done in three main steps:

- The collection of essential data for the identification process, corresponding to the dependencies between the classes and arrived at from a dynamic analysis of the application.
- Identification of the components, in three methods explored: the first one uses a lattice of Galois, the second two meta-heuristics and the last one a meta-heuristic multi-objective.
- Identification of the architecture based on application components, identifying the required / provided interfaces of each component.

The concept of projecting this component-based method in an object-oriented application; can be used as a template to perform a restructuring of an object-oriented application to a similar, component-based, operational application.

d. A formal approach to automate change management in component-based software development processes (2015)

This approach (Mokni, 2015) improves the management of software evolution in component-oriented development processes, adopting a model-driven engineering (IDM) approach, supported by *Dedal*, an architectural description language (ADL), three levels (specification, configuration and assembly) correspond to the three main stages of the development of an architecture (design, implementation, deployment) and keep the signature of the architectural decisions made during development.

This efficient management of the evolution makes it possible to determine the level of a change, to analyze its impact and to plan its realization in order to avoid the occurrence of inconsistencies in the definition of the architecture. Rigorous management of the evolution requires the formalization, on the one hand, of the intra-level relations linking the components within the models corresponding to the different levels of definition of architecture and, on the other hand, inter-level relations linking models describing the same architecture to different levels of abstraction. Relationships and properties are described in B, a formal modeling language based on set theory and first-order logic. They apply to architectures defined with a formal ADL written in B whose meta-model is aligned with that of *Dedal*. This integration makes it possible to propose a development environment combining the advantages of IDM approaches and formal design of architectures with *Dedal* tooling (graphical modeler); Architectural Verification and Evolution Management with B Tooling.

Knowledge Management Approaches

This part is devoted to some management knowledge approaches

a. Modeling behaviors in dynamic systems: Application to the organization and regulation of parking and travel in Urban Traffic Systems (2007)

This work (Boussier, 2007) proposes a methodological framework to model the behavioral changes of individuals as well as their impacts on the state of a complex system in a dynamic context.

Modeling the heterogeneous preferences of users, integrating knowledge, according to different behavioral logics, justified the multi agent approach, in order to have adaptive and evolutionary representations of behaviors.

Individual agents, decision-making and learning processes are modeled using a basket for tools from the optimization of industrial processes, Data Mining techniques, marketing. The personalized use of the simulator with simulator user interactivity motivated the adaptation of this methodological framework to the simulation of complex societal systems.

b. MODELS AND TOOLS FOR CAPITALIZATION OF KNOWLEDGE IN DESIGN: Contribution to management and knowledge engineering at Renault - DCT (2011)

The contribution of this work (Ludovic, 2011) is positioned within the scientific disciplines of the knowledge management and knowledge engineering.

From a theoretical point of view, the analysis of the state of the art, but also the context particular industry in which this work was carried out, led to propose a conceptual model of process-oriented

knowledge preservation. This target model mainly organizations, having chosen a global management approach by the process as recommended by ISO (International Organization of Standardization).

It is based on an original arrangement of scientific concepts strongly inspired by the method MASK (Methodology for Analysis and Structuring Knowledge) developed by Jean-Louis ERMINE (Aries, 2008) and having contributed to the preservation of knowledge . The interest of this model is positioned in a goal to manage, by through a formalization stage, the link that exists between, on the one hand, codified knowledge in documents or knowledge-based applications and on the other hand concrete operational activities. This management is targeted optimizing the quality, costs and delays of redesign processes.

FOCUS OF THE ARTICLE

Essentially, the heart of the problem lies in the difficulty of making the right decisions in the identification and development of components compatible with the requirements and meeting the needs, as well as the management of data and communication between these components.

The objective of this work is to develop a component modelization approach and to make available a manager to take the task of the system easier due to the multitude of information to consider, expressed by:

- A process for developing the system's software components and subsequently the system's architecture.
- A communication management approach between these identified software components representing the different types of users of the system.

Since the role of the components is to provide the business functionality of the system, the proposed approach is to identify the different components of the system, and keep these components throughout the software development cycle.

With the advent of UML 2.0, it has become increasingly easier to express needs and requirements such as (Karaa and al., 2016). The main addition to the UML is the new concepts.

Although originally designed as a notation for object-oriented modeling, UML has great potential for component-based systems. Components applies UML to the world of component architecture, demonstrating how it can be used to specify components, their interactions, and their integration into cohesive systems.

The goal of these approach patterns is to identify and formalize the recurrent design schemas in a context based on the UML architecture design model manipulation tool and to examine their integration into an EJB.

SOLUTIONS AND RECOMMENDATIONS (SECTION 3)

A. Design & Management Method

1. Method of Software Component

With the aim of developing information systems organizing data in an easily accessible way, or well suited to a good decision-making represented in an intelligent way towards the development of a software project, from which it is necessary to define a method of analysis and design of software components.

The data are classified and categorized, without repetition, in the information and their treatments. The study of the treatment of multiple components is generally simpler than the study of the overall treatment of a system, because each simpler component will be the subject of a separate study and simpler to study separately.

The approach according to our point of view must start from the general, and go towards the particular, that is to say a guided by the functionalities of the system; the system is divided into components where each must perform a function (possibly several, if the component is decomposed into subcomponents with separate functions). These components make it possible to organize and cut the system into manageable and exchangeable pieces of software.

The needs analysis enables the identification of strategic and methodological options for developing the functionalities of the components. The decision to break down a system into functionalities increases the number of components, and creates elements that are by default in the initial state, estimated. The decision to break down a system into functionalities increases the number of components, and creates elements that are by default in the initial state, estimated, and accompanies the activity of the actors either at the operational or decisional level. Each method or approach proposes specific steps for each phase. The work in stages as well as their phase facilitates the resolution and constitution of the project. Each of these phases describes dependencies with the other phases and ensures overall consistency and direct system matching during the execution of the approach.

Figure 2. The set of Steps and Models in the proposed Approach process

The desired functions of the modeling component expressing the essential functions of each component are plotted. The clipping here, becomes more detailed in a division into the functions of the parts.

The system is broken down using features that display all the main UML behavior models.

With the advent of UML 2.0, it has become increasingly easy to express needs and requirements such as (Karaa et al., 2016). The main addition to the UML is the new concepts. The system is broken down using features that display the main UML behavior models.

2. Management Component: Organization and Management component of Data and Information

This section deals with a knowledge management model. A good model can integrate various elements and show relationships and dependencies. But first, what are the components of a knowledge management framework.

The models display processes that simulate what actually occurs inside an organization system. The problem with the latter is that they are often hard to grasp and can only convey limited information so as not to become incomprehensible.

Since KM is closely dependent on other information management, project management, etc.). So a model can become very complex indeed.

Efficient management of data and knowledge are key of the success of almost any organization, but also to the successful treatment of condensed of data: with the transition to the information and the knowledge technologies, data has become both increasingly central and critical to all activities. The component processes the data through a set of activities and a library and then through the input / output functions. Component modeling is achieved by a structure consisting of the interface exposing or requesting from the rest of the application some data.

The data are classified and categorized, without repetition, in the information and their treatments. The purpose of managing information systems is for the organization of knowledge existing in information, in an easily accessible manner, or appropriately for good decision-making intelligently represented in the development of a software project.

Software systems are developed by assembling component units that provide a set of exposed services. The role of component services is the communication, the management, the organization of knowledge offered by information and the association of all the links existing between a component and another component.

Figure 3. Assembly via Management Component interacting with the Basic component and Subordinate Components

In order to decouple the management of subordinate components A and B, Management component is interposed between them. Each one invokes the Management component during the execution of the system, at which point the instance receives the call to verify the operation requested (the arrows in Figure 3 request sent and reply received).

The essential role of component-based development is the component model that defines how components can be built and how the information can be communicated and managed.

It's about defining what components the composite is composed of, how these components are interconnected and related to the composite. Composites can also include services and other attributes (Radermacher, 2013).

The steps of Management Component:

- It starts by identifying a basic component
- Then identify its subordinate components (components A and B) (Identify the components the method of the previous paragraph or Article (Rehioui, 2019))
- Interpose between the base component and the subordinate components A and B, another management component.
- The role of the management component is the management of all the links existing between a basic component and another subordinate component.
- Each process is intended to represent a component during system execution.
- Component A invokes process P1, at which point instance "I" receives the call to verify the operation requested by the process.
- The instance "I" invokes the base component, the latter checks the operation to allow or to reject the validity of the operation.
- The instance is an object with a behavior and a state.
- A subordinate component, a process is mapped.
- A set of activities is part of the whole process

The code for creating and managing all these components (and specifying how they interact with the base component) is typically defined in a Management component. This is not because it must be defined there, but because it is **logical** to separate all the information management from the system components.

Basically, it must declare a field `compManagerBase` to hold a reference to the Management component instance. It also sets up a getter to return the instance of the manager component `public ComponentManagerBase getMyComponentManager()`.

Finally, it creates a method to set the management component `compManager` by `setComponentManager(ComponentManagerBase compManager)`.

During work of the Management component, it provides the method `setprocess()` allowing activating/deactivating a process and the method `getprocess()` returning the active process. The active process is either an instance of the system component.

`Boolean ComponentIsSelected(Component comp)` Returns the selected component.

`public void setEnabled(boolean b)` enable / disable a component and there for enable/disable process, components are initially disabled by default.

Class Component extends compManagerBase {

voidComponentIsSelected(){ }

```
protected void setEnabled(boolean b){ }  
  
}
```

As a result, the architecture does not describe what a system needs to do but how it is designed to meet the specifications already built. However, the functional analysis describes the “what to do” while the architecture describes the “how to do”.

Technology (Section 4)

The software architecture expresses software components as part of information system architecture. The notion of component, as a real architectural element for the analysis and design of the information system, aims to divide and identify the system into autonomous, well-defined parts, and describes interactions with other parts.

When a piece of software or a component is created autonomous and well-defined, and describes interactions with other components, it is essential to perform several tests to ensure that the component is complete and efficient. To carry out these tests, several methods and mechanisms of code examination define how to describe abstractions and how to use them afterwards. There are generally three types of examinations: black box, white box and gray box.

The black box is represented in a basic way by displaying the inputs and outputs but by masking its structure and its internal functioning (a code), by examining only the functionalities of an application, that is to say if it does this that it is supposed to do, no matter how it does it from where we check that the end result is suitable via a “user” profile.

The white box aims to analyze a computer program whose exact structure, processes and internal functioning (the source code of the program) is known rather than its functionalities from which one has access to the complete state of the system and thus to have programming skills, in order to understand the code studied via a developer profile, and not a user.

The gray box allows access to certain information of the system state; it reveals properties of the implementation as it is an intermediate solution between the previous two is to consider gray box components. Such as giving an input (input) to a system, check that the output obtained is that expected, and verify by which process this result was obtained. In this case, a subset of the operating modes of a component would be open for modification by means of a set of predefined mechanisms.

The software component designates simple files, generally compiled code, existing in module which delivers a service, via couplings, and makes it possible to pass interactions between these modules. Each module can export or import some data in the form of variables, functions and classes later.

The era of component-oriented began to grow 30 years later by Sun EJB (Sun, 2018) OMG (OMG, 2018), Corba Component Model (CORBA, 2018), Microsoft “.NET / COM.” (Microsoft, 2018) etc. To benefit from technological advances, it is essential to adapt applications to technologies. The implementation is the culmination of the design to adapt the system as components, i.e., source code, scripts, and other elements. The main targets of the implementation are to plan the component embeddings for each recurrence, and to produce the classes in source code forms.

As a result, the architecture does not describe what a system needs to do but how it is designed to meet the specifications already built. However, the functional analysis describes the “what to do” while the architecture describes the “how to”.

The most general and the oldest is usually CORBA which suits the model of these applications. However, the heaviness and the complexity of implementing this type of application are the major disadvantages of this technology. This is why a more restrictive but powerful model has emerged: the EJB model.

EJB is this type of component that is particularly interested in business requirements through remote objects. These EJBs serve as an intermediary between windowed applications, or Web applications, and the database.

The code of a component is indeed separated into two categories; internal methods and data. One component implements “private” methods of non-externally accessible functions and “for personal evaluation”. To use them, the component must provide a means of communication with the client programs.

Specifically, an EJB component is a set of Singleton type classes and an XML file to configure it. Classes must meet a certain specification (the Stateless or Statefull EJB specification, which can be called locally, or remotely (via RMI) to execute methods), and all of which must be in a single file to form an entity.). These components, like beans, can be accessed by all types of clients: servlets, JSPs, Java clients via Java RMI (RemoteMethod Invocation). What characterizes them is the need to be in a container, called an EJB container.

It is necessary to distinguish between the categories of these components:

- **Session EJBs:** This type of bean serves one client at a time and can be seen as an extension of the client at the server.
- **Entity EJBs:** Entity beans represent data that originates or feeds the database according to a data object model. They can be accessed by multiple clients simultaneously.
 - **MessageDriven EJBs** represent a queue of messages posted by the client and processed by the server (or vice versa).

A “User class” that is transformed into an EJB by adding the @Entity annotation and having a session EJB for this entity, transforming a simple javabean into an EJB by adding the @statefull or @stateless annotation.

Some “public” or “interface” methods of externally accessible functions are intended to be called by client programs.

The interactions between the EJBs and the application server are provided by notations in order to simplify the implementation of the interfaces.

```
import java.sql.Date;
```

```
import java.util.List;
```

```
import javax.ejb.Local;
```

```
@Local
```

```
public interface LibraryManagerBeanLocal {

}
```

```
package sessions;
```

```
import java.sql.Connection;

import javax.ejb.Stateless;

import java.sql.Date;

import java.sql.DriverManager;

import java.sql.ResultSet;

import java.sql.ResultSetMetaData;

import java.sql.SQLException;

import java.sql.Statement;

import java.util.List;

@Stateless

public class LibraryManagerBean implements LibraryManagerBeanLocal {

    Connection con = null;

    Statement sta;

    ResultSet re;

    ResultSetMetaData metaData;

    .

    .

}
```

FUTURE RESEARCH DIRECTIONS

The management component approach provides a methodological idea, which leads to the development of a suite of controlled and managed components to reduce data redundancy. The future goal is to identify the typically and efficiently different parts to successfully complete the approach.

After component technology and assembly, the MDA approach (Kherraf, 2011) comes to produce models that are not only for visualization or communication, in the MDA approach, for generating and producing.

It is no coincidence that the notion of component gives a great interest in the development of complex systems. Currently, the research focuses on the complete definition of component-based information systems approach design. This type of research should lead to a real and effective method of engineering field.

CONCLUSION

The notion of software components is interested in problems such as the lack of coherence between the breakdowns of the system and the lack of traceability during the software development cycle, that are not taken into account until now.

The state of the art shows all the methods, approaches and processes aimed at undermining the complexity of the field. Moreover, the concepts are far from having a definition adopted by all, starting with the founding component. Methodological solutions based on components are in full emergence, and have shown their limits, to form simply composable entities. Software systems are developed by assembling component units that provide a set of exposed services as interfaces. The essential role of component-based development is the component model that defines how components can be built and how they can be assembled.

Currently, the research focuses on the complete definition of a component-based information systems design approach. This type of research should lead to a real and effective method of domain engineering. The goal to be achieved is to define a method of designing components in the modeling of complex systems.

The design of systems based on components supposes to mean for modeling its data management. The concept of Management Component is one of these means.

This presented approach allows the design of a software Management component by assembling a basic component and its subordinate system software components.

This approach starts with defining the different elements of the Management component whose function is to generalize all the characteristics of subordinate system components, and to forward requests from the base component. Also, it has the role of monitor and ensures the system changes state via the corresponding process and an instance of the component.

This pattern offers a good adaptation to the concept of the management and communication between the components, because it allows the system to communicate according to its priorities.

Methods are generally presented a particular vision of how to develop software, and they do not say how to program; these are processes that provide steps to drive development.

Finally, this work is aimed at software engineering researchers, who are familiar with Component-oriented Analysis, Design, and Management and want to obtain an overview of the technologies that are enabling component-based development.

KEY TERMS AND DEFINITIONS

Base Component: It is the first common component that includes the features and common functionalities between the different components, accessible by every user, also called default component because it is the unique component that is activated when no component of the system is enabled.

Component: It is a data concept informally corresponding to a list of activities, providing the business functionality of the system.

Data: Facts and numbers which relay something specific, but which are not organized in any way and which provide no further information.

EJB Component: It's this type of component that is particularly interested in business requirements through remote objects. These EJBs serve as an intermediary between windowed applications, or web applications, and the database.

Information: when data become contextualized, calculated, its called information.

Knowledge: Knowledge is contextual information that provides an environment and framework for evaluating and making decision and information. In organizations, it often becomes implanted in documents, practices.

Management Component: Mediator component to manage all operations and to react and interact with other components. Its role is the management of all associations and links existing between a base component and the other subordinate system components, the management of the ability to communicate units.

Modelization: The process of modeling, constructing on the base of the function should give the functional modelization of the system, based on the conceptual function.

Subordinate Component: Is performed by a structure consisting of the interfaces offering or requesting some data from the base component of the application.

An Introduction to Clustering Algorithms in Big Data

INTRODUCTION

In Big Data, clustering is the process through which analysis is performed. Since the data is big, so it is very difficult to perform clustering approach. Big data is mainly termed as petabytes and zeta bytes of data and high computation cost is needed for the implementation of clusters. In this chapter we will show how clustering can be performed on Big Data and what are the different types of clustering approach. The challenge during clustering approach is to find observations within the time limit. Chapter also covers the possible future path for more advanced clustering algorithms. The chapter will cover single machine clustering and multiple machines clustering which also includes parallel clustering.

Today, data is increasing rapidly which actually forms a big data due to its high velocity, huge volume and different varieties of data (Shobana & Kumar, 2015). Few years before we are dealing with data collection challenges, but now in this era we are more concerned with processing this huge amount of data or big data (Nair & Bhagat, 2018a). Big data is analyzed for prediction and analysis purpose (Tsai, Lai, Chao, & Vasilakos, 2015). Scientists and researchers believe that today one of the most important topics in computer science is Big Data, whether the data collected through social networking websites, ecommerce websites or any other websites which is having accessibility to billions of users. YouTube has more than 1 billion users which is producing almost 200 hours of video in each hour and its content ID service scans over 400 years of video every day. Main reason behind storing these types of data is further used for knowledge discovery (Chu, 2013). Data mining is the method which is mainly used for knowledge discovery and clustering is the process which is used for dividing the data into groups that contain objects of similar patterns (Chu, 2013). Clustering is vastly used in many areas such as bio-informatics (Y. Q. Zhang & Rajapakse, 2008), machine learning (Kubat, 2017), pattern recognition (Neal, 2007), networking (Sucasas et al., 2016) and lot of research work is done in this area. A decade before clustering algorithm was applied on small data in order to handle their complexity and computational cost, this also increased the speed with scalability. Due to occurrence of Big data in recent years more challenges are added to perform clustering.

Big Data Challenges With its Important Characteristics

Big data is the phenomena which mainly work on 5 v's (Saporito, 2013), which is volume, velocity, variety, value and veracity, but it is not limited to 5 v's it can be extended further also. Normally Big data is unstructured, this means data cannot be easily transformed in the form of rows and columns and this

DOI: 10.4018/978-1-7998-3479-3.ch040

cannot be processed by traditional databases. So to process this Big Data, NoSql database (Lourenço, Cabral, Carreiro, Vieira, & Bernardino, 2015) are used. Let's discuss these V's one by one.

- **Volume** – This term is directly related to space occupied during data storage, whenever there is talk about big data, volume is the main aspect. Today most of the application are based on big data like data collected by Facebook which is having more than 2 billion users, data collected by traffic sensors, data collected by aero plane during transfer travel from one place to another, data collected by ecommerce website, data collected by Youtube having one billion users etc,. The amount of data collected is more than terabytes can be considered as big data but there is no limit defined to which we can say the data is big data.
- **Velocity** – This term is directly related to speed of incoming data which means when we are uploading the data at some specific server, in that case it may happen that many people are accessing that server at a time, so it experience a high speed. In case of facebook, 900 million photos are uploaded, 500 million tweets posted on twitter, more than 3.5 billion searches performed in google, 0.4 million hours videos are uploaded on Youtube. The incoming speed is just like nuclear explosion, so Big Data processing help us to deal with this high velocity of incoming data.
- **Variety** – Many of the website applications has to process and analyze different varieties of data like text, image, video, etc. and it is not an easy task to process different varieties of data. Facebook is the best example where we deal with different varieties because different users used to post textual data, images and videos at the same time, so facebook has to handle these varieties of data and later on processing should be done. To process this Big Data plays an important role.
- **Veracity** – It relates to trustworthiness of the data means the data which is collected that is reliable or not even it can be said that it is accurate or not. Veracity is very much needed during processing of big data because if we process the inaccurate data, in that case the analysis will also be inaccurate.
- **Value** – Finally the last V i.e. value which actually transforms the data in the form of value. In the complete chapter we will discuss the challenges, methods and applications of clustering in detail with respect to big data. It's mainly related to cost or profit included in the system in terms of value.

Figure 1. 5 V's of Big data

Applications Based on Big Data

In today's world many companies are dealing with Big data, Some of the well know industries are given below:

- **Public Administration** – Most of the governmental organization is collecting data from different areas like, Query about government projects, complaint about the government services, transportation system and many more. Government is already investing lots of money and time to process this big data (Schmid, 2017).
- **Healthcare and Social care** – Healthcare industry is one of the growing industry in the area of Big data because the data i.e. collected is mostly in the form of images and videos, it can be like patients MRI images or videos related to operations of the patients. This way huge amount of data is collected and it has to be processed in very less time. There can be other textual data also which will be in the form of like medical report of the patient, complaint regarding to service of hospitals and many more (Rahman, Slepian, & Mitra, 2016).
- **Transport and logistics** – Today most of the transportation and logistics are GPS enabled though which one can easily track the location of the objects. But at the same time these objects are collecting large amount of data and it depends that they may be processed or not. If any issue occurs like accident, then definitely it will be analyzed otherwise it depends on the conditions (Nair & Bhagat, 2018b).
- **Retail and Trade** – Considering retail and trade, e-commerce is the best example and it is used by many people for selling and buying. Large amount of data is collected during the process done in e-commerce like surfing for product, purchasing, selling, reviews for the products, product details, customer information, etc (Aktas & Meng, 2017).
- **Geographic information system (GIS)** – GIS industry has its own nomenclature when dealing with big data and named it as Spatial Big Data (SBD). They are also facing the problem of huge volume, variety and update frequency, which cannot be handled by usual spatial computing techniques, architecture, methodologies and software solution. Nowadays big data processing techniques are used for GIS (Wu, Zhang, & Gong, 2014).
- **Media and Entertainment** – Another broad area of big data, in this huge amount of data is collected in the form of news paper content, audios, videos and many more. Polling and reviews are also stored in the form of data. A popular websites IMDB that contains all the details of all the movies which are released today anywhere in the world. It contains the ratings, reviews and all the information related to movie (Mahrt & Scharkow, 2013).
- **Application and Services** – Most of the application and services based company are collecting huge amount of data in the form of user's details, reviews, request and the operations done by user (Dobre & Xhafa, 2014).

BACKGROUND

Before discussing the specific techniques of clustering, this section will provide some necessary background, first we will define the cluster analysis after that illustrate the problems during cluster analysis and describe its relationship with other techniques that group the data.

Cluster Analysis

In order to extract data from Big Data, cluster analysis is very much needed. This is the place Cluster Analysis systems can characterize and group the objects based on attributes. Cluster Analysis looks to apply a typical way to deal with collected objects on the basis of their relationship to each other and by accessing the structure generated by the user selected characteristic. It is a nonexclusive name for a gathering of multivariate data analysis techniques that use a cluster variate, a scientific representation that compares the similarity of objects. Cluster analysis is widely used in pattern recognition, by recognizing data patterns analyst can reduce the number of observation which he has to make and can predict some hypothesis about the structure of the problem which has to be tested.

Clustering analysis is especially helpful in situations identified with selecting between various business choices, where the choice relies upon the similarity (or contrast between) groups. It very well may be applied to portraying or delivering a scientific classification of objects, for rearranging information where there are numerous perceptions, or for distinguishing connections between items. Regular business models incorporate client division, utility or power utilization and client conduct profiling. Advanced clustering strategies are likewise utilized in more mechanically advanced applications like picture, number plate or facial acknowledgment frameworks, however the standard of classification dependent on a known or assumed cluster variate continues as before. Now in the next section we will see the clustering approaches used in big data.

FOCUS OF THE ARTICLE

The focus of this article is based on clustering algorithms in big data. Let us discuss these algorithms in brief

Clustering

Clustering is mainly used in data mining for analysis purpose, in which similar elements are grouped together. Machine learning is classified into two main categories one is supervised and the other one is unsupervised (Kotsiantis, Zaharakis, & Pintelas, 2006). Clustering comes under the category of unsupervised machine learning which is used as a statistical analysis in many fields. Clustering analysis is used to gain some useful insights from our data by identifying the group in which the particular data belongs. Generally big data clustering is classified into two categories one is single machine clustering and the other one is multiple machine clustering. Nowadays multiple machine clustering has gained a lot of popularity due to its flexibility in extension and it offers faster response to users during processing. In the below section we have shown the different techniques based on these clustering categories. Sample based techniques (Daszykowski & Walczak, 2010) and dimension based techniques (Bouveyron & Brunet-Saumard, 2014) are based on single machine clustering, parallel (W. Y. Chen, Song, Bai, Lin, & Chang, 2011) and map-reduce (Rasheed & Rangwala, 2013) are based on multiple machine clustering.

Let's discuss the figure in detail,

1. **Single Machine clustering** - This clustering is perform on single system and easy to implement. This clustering is fruitful when fewer amounts of data is available and handling of data can be done by single system.

Figure 2. Classification of Clustering Algorithm

- Sampling Based Techniques – These algorithms work on sample from the large dataset that means clustering will be performed on sample and then generalize to complete dataset. This was the first method which attempts to improve the speed and scalability and it is dealing with exponential search space. Computation speed is high due to less amount of space required during clustering operation and complexity also decreases due to small amount of data. Some of the algorithms based on sampling technique are as follows:
 - (i) Clustering Large Applications based on Randomized Sampling (CLARANS) – Before CLARANS there are some more algorithms like PAM (Partition Around Medoids) (Van der Laan, Pollard, & Bryan, 2003) are introduced but these are not sufficient for large data set clustering. So to perform large dataset clustering CLARANS is introduced that decreases the overall quadratic complexity and time requirements into linear in total number of objects. PAM used to calculate the entire pair-wise dissimilarity matrix between objects and store it in central memory but in case of CLARANS there is no need to compute dissimilarity matrix. It is considered as a graph searching problem in which each node is considered as possible clustering solution and criteria for combining two nodes is that they should differ in 1 out of k medoids. CLARANS aims to find a local optimal solution by investigating the entire graph and during iteration this only checks a sample of neighbors of the current node. Dynamic sampling is done at iteration of the search procedure due to which CLARANS has improved performance over CLARA and PAM.
 - (ii) Balanced Iterative Reducing and Clustering using Hierarchies (BIRCH) – It's an unsupervised learning algorithm used to perform hierarchical clustering particularly over large datasets. The main advantage of BIRCH is its ability to form a best quality cluster for the given set of points through incremental and dynamic approach. If the size of the

processing data is larger than the memory size, in that case computational cost will also get increases in the form I/O devices. This algorithm uses its own data structure called as clustering feature (CF) or clustering tree. Clustering feature is a triplet that contains the number of points in the cluster, the linear sum of the data points and the square sum of the data points in the cluster. It assumes that not always all points are equally important for clustering and at the same time it is not needed that all the points has to be loaded in main memory. If clustering feature satisfies the additive property then two clusters can be merged together, the CF will be sum of the CF's of the other two clusters. This algorithms works in two steps: first it scans the data points and then builds a memory tree according to those points. Secondly cluster algorithm is used to cluster the leaf nodes. According to (T. Zhang, Ramakrishnan, & Livny, 1996) BIRCH performs better than CLARANS and it is adaptive for handling outliers. Given below figure 3 shows how BIRCH algorithm works.

Figure 3. Steps in Birch algorithm

- (iii) CURE: The above two discussed algorithms focus on the points and later on they are considered as clusters, these algorithms performs well only when the clusters have spherical shape. While dealing with real time applications most of the clusters form complex shapes. To handle these complex shape clusters, CURE (Clustering by using representatives) algorithm has been evolved that uses a set of well scattered data points to represent a cluster. CURE is also a hierarchical clustering algorithm that considers single data point as cluster and continuously combines two existing clusters until it reaches to precisely k remaining clusters. The selection of clusters for merging are based on the calculated minimum distances between the possible pair of representative points from the existing cluster. CURE uses two data structures for efficient search one is heap and the other one is k-d tree, heap is used to track the distance for each existing cluster to its neighboring cluster and k-d is used to store all the representative points contained in the cluster.

This algorithm is mostly used for large databases, it solve the problems by applying two main methods, sampling and partitioning. Sampling method is used to speed up the computation during cluster formation. It draws the sample from the large dataset and applies the procedures on these sample data.

To decide the sample size Chernoff bound is used in original work. After sampling, still it is observed that data size is very big and it cannot be processed by simple clustering method, in that case partition methods will be applied to accelerate the algorithm. Suppose there is X as the original dataset, X^1 as the sample data that is divide into y partitions and in each partition it applies the partial hierarchical clustering until it achieves a predefined number of clusters or the distance between two clusters meet the certain threshold value so that they can combine or merged. Now clustering runs and passes on all partial clusters from all the y partitions. Performing all these steps, at the final stage, all the non-sample data points will assign to nearest clusters. Results show that CURE algorithm (Guha, Rastogi, & Shim, 2001) have lower execution time than BIRCH and it also maintain the privilege of robustness during handling outliers by compressing the representative points to the centroid of the cluster with a constant factor.

Figure 4. Steps in CURE algorithm

- **Dimension Reduction** – Normally big datasets are high dimensional datasets, so when we are dealing with high dimensional datasets in that case consumption of time and complexity gets increases (Donoho, 2000). It is very much needed that dimensions should be reduced so that speed and performance of clustering gets increased. The above explained sampling method only reduces the dataset sizes but the dimensions will remains same. To reduce the dimensions there are mainly approaches two approaches, random projection and local projection.
 - (i) **Random Projection (Locality-Preserving Projection)** – Transformation in dataset is done from d dimensional to lower dimensional space, during this pair wise distance is preserved. Most of the clustering algorithm is distance based and it is assumed that clustering formed from the resulted projection is approximately equal to the original clustering space. Linear transformation of original matrix is performed for random projection, let M be an original matrix and R be a rotation matrix of $d * t$ (t is dimensions, $t < d$) and its element $R(i, j)$ be independent random variables is transformed to $M' = M.R$ that contains x dimensions which is very less than t . M' is projection of matrix M with x dimensions. Although in case of random projection construction of rotation matrix is different. There can be many more methods for performing random projection. After transforming projected matrix into lower dimensional space, clustering can be accomplished (Shikkenawis & Mitra, 2016).
 - (ii) **Global Projection** – In this projection the main aim is to find the data point which is to be projected as close as to the original data point which is unlikely to random projection that works on the concept of maintaining the same pairwise distance between the points for the projected space as that of original space. If the original matrix is M and M' be the projected matrix then according to global projection the aim is to find $|M' - M|$.
- 2. **Multiple Machine Clustering** – Above discussed sampling and dimensional reduction algorithms are based on single machine clustering that also increases the scalability and speed of the algorithm. But nowadays what we have observed that the data which is collected is very huge as compared to data collected 10 years before, they are in terabytes and petabytes, which needs faster memory and processors and this cannot be handle by single processor and memory. Due to this high storage processing problem, there is requirement of multiple processor and need of algorithms that can run on multiple processors. This technique allows huge data into smaller pieces which can be loaded into different machines and utilize their processing power for computation of individual result. To perform this operation multiple machine clustering algorithm is classified into two categories:
 - **Parallel Clustering Algorithm (Un-automated distributing)**
 - **Map reduce Clustering Algorithm (Automated distributing)**

Above figure shows hoe clustering is done through multiple machines, here data D is split into $D1$, $D2$, $D3$ and $D4$ and they are processed individually after that we combine the individual results R , so that they can form the cluster.

In case of parallel clustering, load distribution is of the most important process, because other than parallel processing challenges you have to distribute your load to different machines depend on their capability which make complicated and time consuming. Comparing to parallel clustering approach, map reduce approach is better because it allows programmers to work comfortably and reduce the burden of programmers related to load distribution, unnecessary networking problems, fault tolerance etc. Due to these automatic features the parallelism is achieved easily in very less time. Parallel and distributed

Figure 5. Multiple machine clustering techniques

Figure 6. Lifecycle of multiple machine clustering algorithms

algorithm (Dhillon & Modha, 2007) have some of the common characteristics like, dividing the large dataset into small size data set and processing these small datasets in multiple machines individually to form a small clusters. These small clusters are combined together which later on try to form a bigger cluster. The bigger challenges that they face are minimizing the data traffic and less accuracy as compared to serial processing. Given below figure will represent the cluster formation during parallel strategies.

Lesser accuracy might be achieved due to following two reasons, one is applying different algorithms in different machines and second one can be applying the same algorithm in multiple machines. In some case divided data can change the final observation of clustering.

- Parallel Clustering - Comparing to serial clustering, parallel clustering is difficult to implement but it provides speed and scaling of clustering algorithms. Now we will see some of the well known parallel clustering algorithm (W. Y. Chen et al., 2011).
 - (i) DBDC (Density Based Distributed Clustering) – The main objective of DBDC is to form clusters of arbitrary shapes. High density of points is maintained inside the cluster than the outside cluster points but the noise region is more inside as compared to outside of the cluster. This algorithm almost follows the steps shown in above figure 6. At the individual clustering level they use some defined algorithms and at general clustering level they proposed DBSCAN i.e. a single machine based clustering algorithm for computing the final result. It is sure that even DBDC maintain the same clustering quality as that of DBSCAN but when it comes to speed it run almost 30 times faster than the serial approach (Januzaj, Kriegel, & Pfeifle, 2004).
 - (ii) ParMETIS – This is another parallel processing algorithm based on METIS for distributed system. METIS is a multilevel partitioning algorithm. Mainly there are three phases in ParMETIS that are coarsening, partitioning and uncoarsening. According to first phase maximal matching on the actual graph is performed after that similar vertices are combined together to form reduced graph. This process until we reach to some minimum number of vertices. Now the second phase in which multilevel recursive bisection algorithm is applied on the k-way partitioning of the graph obtained from the first phase i.e. coarsened. In the last phase i.e. uncoarsening, the greedy retirement algorithm is applied to project the partitioning of the second phase to the original graph. Although this above paragraph discussion is about METIS but these given three phases are used in ParMETIS also and this algorithms is considered as distributed approach of METIS. ParMETIS uses graph for formation of clusters, it does not follow the general cycle for distributed and parallel clustering which is discussed above. This algorithm was mainly designed for clustering and partitioning graphs that occur in various computational science applications and it not much suited for social networking applications which consist of millions of vertices and edges in the graph due to its limited amount of memory (Sui, Nguyen, Burtscher, & Pingali, 2011).

ParMETIS method performs coarsening and uncoarsening operations that are considered to be graph operation and this makes them different from other clustering approaches. At initial stage each processor receives an equal number of vertices, in the next phase i.e. coarsening in which graph coloring process has been done and then global graph is computed by incrementally matching the vertices of the same color one at a time. Now at the partitioning phase all the coarsened graph is broadcasted to all the machines, after receiving the graph each graph will performs recursive bisection by exploring the single path of the recursive bisection tree. In the last phase i.e. uncoarsening, same color vertices are used for movement, subset of these vertices leads us to reduction in elements. During movement process not all the vertices move, only the selected vertices through ParMETIS will move and this helps in the reduction of communication cost. It has been observed that running time of PerMETIS is 15-35 times faster than serial algorithm when computation is done using 128 processors.

Clustering Approach Through Graphics Processing Unit (GPU)

In recent times parallel processing has gained a lot of importance due to their high computation speed, to perform this GPU (Graphics Processing Unit) is widely used. GPU has more processing power than CPU (Buluç, Gilbert, & Budak, 2010), this is the reason nowadays all the applications are using GPU whether it is Machine learning, deep learning, Image processing, data analytics or blockchain (Morishima & Matsutani, 2018), almost all of them are using GPU. Clustering algorithm is also proposed using GPU i.e. based on DBSCAN named as G-DBSCAN (Andrade et al., 2013), it's a GPU accelerated parallel algorithm for density-based clustering algorithm. This algorithm use graph based data indexing to add flexibility and this increase parallelization process. G-DBSCAN algorithm works in two steps and both the steps has been parallelized. In the first step construction of graph is done in which each object represents a node and an edge is created between nodes on the basis of distance or some predefined threshold value. After the construction of graph, the second step is identification of clusters, to perform this Breadth First Search (BFS) is used to traverse the graph that has been created in the previous step. It has found that in comparison to serial implementation, G-DBSCAN is almost more than 110 times faster.

- **Map Reduce** – Above discussed parallel clustering algorithm provides us the scalability and increase in speed, despite all these advantages there is big challenge during dealing with memory and distribution of objects to different processors. To overcome from these challenges Google introduced the framework known as MapReduce (Dayalan, 2018). Hadoop uses MapReduce for processing BigData. The improvement by using MaReduce is shown by three factors, which are Speed-up, Scale-up and Size-up.

Figure 7. Map-Reduce framework

- Speed-up: This factor relates to the ratio of execution time when dataset size remains constant and number of machines gets increased.
- Scale-up: When machine size gets increase in that case if job size also get increase with same execution time.
- Size-up: If the number of machines remain constant, in that case during increase in data size will increase the execution or running time linearly.
 - (i) Parallel K-means clustering (MapReduce based K-means) – This clustering is distributed version of K-means clustering. K-means is one of the best clustering algorithm used in serial clustering system, which divides the whole dataset n into k clusters ($n \gg k$). Initially it assumes all the n points are independent of each other and select K random points as a cluster and calculate the nearest points from each cluster by computing the Euclidean distance between the points and the cluster. After forming the k clusters of n points, now it updates the centre of each cluster with mean of the instances. These steps will be applied repeatedly till it achieves the correct form of cluster.

PK means also work on the same concept but it runs on multiple machines with slight changes, it distributes computation to multiple machine by using MapReduce approach to enhance the computation speed and scaling of the process. As discussed above MapReduce is a two-step process, so in the first phase individual cluster will be formed using mapper method and in the second phase the entire individual clusters will be merge to form general cluster using reducer approach. It also exhibit linear speed-up and size-up property with good scaling (Zhao, Ma, & He, 2009).

- (ii) MR-DBSCAN: This is another recent map reduce approach algorithm based on DBSCAN, that overcome the limitations exist in parallel DBSCAN algorithm. Main problems occur in the parallel DBSCAN are:
 - (i) Balancing during load distribution to multiple systems.
 - (ii) Some of the critical procedures are not enough parallelized due to which there is problem in algorithm scalability.
 - (iii) Less portability is another problem occurs due to their architecture and design.

MR-DBSCAN is the other partitioning algorithm based on DBSCAN which achieves fully parallelism with cost efficient scalable approach. Some of the experiments have shown how MR-DBSCAN works efficiently on the large dataset as compared to other algorithms.

MapReduce based on GPU - GPU's are much more efficient than CPU, using MapReduce with CPU provide efficient framework for distributed computing but performance can be improved in terms of speed and scalability by using GPU (He, Fang, & Luo, 2008). Another algorithm is also proposed based on the concept of MapReduce framework that can run on multiple GPU's named it as GPMR (Stuart & Owens, 2011). Still it is in the development stage but many researchers claimed that due to rapid increase in data, this type of algorithm will be useful for more fast and scalable clustering.

FUTURE RESEARCH DIRECTIONS

This section will discover some of the areas related to clustering in which future research can be done

- Clustering techniques have done good job for clustering numeric datasets by fundamentally improving the base clustering algorithms but still lot of work has to be done for the mixed dataset (Vega-Pons & Ruiz-Shulcloper, 2011).
- Different mixed datasets in application areas, for example, medicinal and socio-financial matters contain uncertain information due to improper data acquisition methods or inborn issues in the information procurement. Clustering uncertain mixed data is an important future research in different domains.
- Some of the researchers have developed methods which can convert the mixed dataset to pure numeric dataset (Wei, Chow, & Chan, 2015). This is again the difficult problem of mixed data clustering and it has been observed that during conversion there is always a loss of information, so this has become the aspect for future research.
- It has been noticed that real world mixed data is imperfect, one of the reason for this imperfection is missing values. However some of the methods are developed which can compute mixed values for the mixed data and can perform clustering (Audigier, Husson, & Josse, 2016). The other approach which is developed to handle these missing data is clustering algorithm through their objective function (Hunt & Jorgensen, 2003). Although these approaches are not enough capable to handle the real world problems, so these missing values are creating the scope for the research.
- Another outcome of big data is guaranteeing the scalability of clustering algorithm to make them helpful in real world situations. Parallelization of mixed data clustering algorithm is a feasible methodology to enable them to scale with expanding information size and keep up linear time complexity (particularly for partitional clustering) (Subramaniaswamy, Vijayakumar, Logesh, & Indragandhi, 2015). Dynamic research around there is required to keep the field in synchronization with huge information challenges. So also, growing quick and precise web based clustering calculations to deal with huge streams of mixed information expects regard for location inadequacies. These incorporate low grouping quality, assessment of new ideas and idea float in the fundamental information, troubles in deciding cluster centers and poor ability to manage anomalies (J. Y. Chen & He, 2016).
- Another rising region of research is formation of clusters with deep learning algorithms (Min et al., 2018). The goal (loss) of deep learning clustering methods is to find deep networking loss and clustering loss. Consequently, these techniques differ as per the network architecture or on the types of clustering technique, (for example, partitional or hierarchical). However these methods are mainly applied for numeric datasets so there is a great opportunity to work with mixed data clustering with deep learning algorithms.
- It become complex when there is increment in space and size, most of the machine learning algorithms lose their interpretability and might be treated as a black box. Even mixed data clustering are not exception. Clustering models that are simple to disclose is alluring to professionals, for example, clinicians, business experts, geologists, and researcher. Interpretable models can help them in making educated choices. Tragically, just a couple of specialists have investigated this zone of creating interpretable mixed data information clustering strategies to address basic parts of the models. There has been late research in the field of highlight determination for mixed information (X. Zhang, Mei, Chen, & Li, 2016); in any case, consolidating such outcomes with clustering has not been tremendously investigated. Selecting a subset of relevant features can possibly upgrade the interpretability of clustering algorithms too.
- Spectral clustering produces great outcomes and doesn't require solid assumptions about the insights of the clusters. Spectral clustering has been utilized to group mixed datasets. The similarity

matrix is the initial step of Spectral clustering. During spectral clustering for mixed datasets builds up its very own similarity matrix (Niu et al., 2016).

- Subspace clustering is a feasible way to deal with clustering of big data with high-dimensional mixed data, however the huge information issue in itself is testing. The expansion of other subspace clustering approaches, for model, network based techniques for mixed datasets is vital to improvement of clustering algorithm for high dimensional mixed datasets (L., E., & H., 2004). In subspace clustering, an information point can have a place with more than one group and subspaces. Research on adjusting other subspace clustering approaches that have been produced for numeric datasets, for example, correlation clustering, ought to be stretched out to mixed data clustering (Immerlica & Wirth, 2008). Specifically, utilizing the connection between's numeric and categorical features to make subspaces are an inventive research zone.
- Integration of space information into clustering is a significant research region as this can improve the clustering accuracy and interpretation. Constrained clustering is a way to deal with taking care of these types of issues. Constrained clustering for iterative partitional clustering techniques has been proposed for mixed datasets (Wagstaff, Cardie, Rogers, & Schrödl, 2001). Although, there has been no research in the area of constrained clustering with other clustering algorithm like hierarchical and density-based clustering. With the availability of large scale information, there is a need to develop clustering algorithm for mixed data that can use this learning to make accurate and interpretable clusters.
- Many of the clustering algorithms require client side parameter, that's why final clustering results are based on these parameters, which incorporate number of desired clusters and initial clusters for iterative partitional clustering algorithm and the model determination for model-based clustering. A few endeavors have been made to create parameter free clustering algorithms for mixed datasets (Böhm et al., 2010). Still the research in this area is open.

CONCLUSION

It is well known that data will get increased day by day, this indicates that complexity will also get increases. So it is very much needed that there must be technology upliftment in this area which can minimize the complexity. It will always be a challenge to maintain scalability during clustering due to this rapid increase in data. In this chapter we have discussed about the clustering approaches used for data processing which includes serial clustering, distributed and parallel clustering and GPU based clustering. In the future it might be happen that integration of the above discussed algorithm will make a new clustering algorithm to gain a speed and scalability.

KEY TERMS AND DEFINITIONS

BIRCH: This is a clustering algorithm which deals with large datasets.

DBSCAN: It's an algorithm based on grouping together points that are close to each other based on a distance measurement (usually Euclidean distance) and a minimum number of points.

GPU: GPU stands for graphics processing unit is a single chip processor mainly used for fast processing.

High Dimension: A big data is considered to be high dimensional as it contains many features.

Machine Learning: It is an application of artificial intelligence that incorporate the ability to learn automatically in the system.

Parallel Clustering: Fast processing can be done through parallel clustering and it can be done with the help of GPU.

PK-Means: It is an algorithm for gene clustering.

Challenges in Big Data Analysis

5

M. Govindarajan

Annamalai University, India

INTRODUCTION

Recent years big data has been accumulated in several domains like health care, public administration, retail, biochemistry, and other interdisciplinary scientific researches. Web-based applications encounter big data frequently, such as social computing, internet text and documents, and internet search indexing. Social computing includes social network analysis, online communities, recommender systems, reputation systems, and prediction markets where as internet search indexing includes ISI, IEEE Xplorer, Scopus, Thomson Reuters etc. Considering this advantages of big data it provides a new opportunities in the knowledge processing tasks for the upcoming researchers. However opportunities always follow some challenges.

To handle the challenges, various computational complexities, information security, and computational method are needed to be known to analyze big data. For example, many statistical methods that perform well for small data size do not scale to voluminous data. Similarly, many computational techniques that perform well for small data face significant challenges in analyzing big data. Big Data problems such as Heterogeneity, Scalability, Storage and Processing Issues, Noise Accumulation, Spurious Correlation, Incidental Endogeneity, Data Access and Sharing of Information, Quality of Data, Fault Tolerance, Speed/Velocity, Accuracy, Privacy and Security, Garbage Mining, Timeliness, Human Collaboration are to be addressed to design effective statistical procedures for exploring and predicting big data. These issues are discussed briefly in the following subsections.

BACKGROUND

David Lazer et al., (2009) discusses an emerging field that leverages the capacity to collect and analyze data at a scale that may reveal patterns of individual and group behaviors. Stadler et al., (2010) developed an efficient EM algorithm for numerical optimization with provable convergence properties. High dimensionality also gives rise to incidental endogeneity, a phenomenon that many unrelated covariates may incidentally be correlated with the residual noises. The endogeneity creates statistical biases and causes model selection inconsistency that lead to wrong scientific discoveries (Liao and Jiang, 2011; Fan and Liao, 2012). Jianqing Fan et al., (2013) gives overviews on the salient features of Big Data and how these features impact on paradigm change on statistical and computational methods as well as computing architectures. Nawsher Khan et al., (2014) comprehensively surveys and classifies the various attributes of Big Data, including its nature, definitions, rapid growth rate, volume, management, analysis, and security. This study also proposes a data life cycle that uses the technologies and terminologies of Big Data. Future research directions in this field are determined based on opportunities and several open issues in Big Data domination. These research directions facilitate the exploration of the domain and the development of optimal techniques to address Big Data. Lenka Venkata Satyanarayana

DOI: 10.4018/978-1-7998-3479-3.ch041

(2015) provides an in-depth analysis of different platforms available for performing big data analytics. This paper surveys different hardware platforms available for big data analytics and assesses the advantages and drawbacks of Big Data. D. P. Acharjya et al., (2016) explore the potential impact of big data challenges, open research issues, and various tools associated with it. Akhil et al., (2017) analyzed the potential effect of big data challenges, open research issues, and different tools related with it. Ripon Patgiri (2018) presents a study report on numerous research issues and challenges of Big Data which is employed in very large dataset. Reihaneh H. Hariri et al., (2019) reviews previous work in big data analytics and presents a discussion of open challenges and future directions for recognizing and mitigating uncertainty in this domain.

FOCUS OF THE ARTICLE

The purpose of this chapter is to highlight the Big Data challenges and also provide a brief description of each challenge.

Heterogeneity

Big data are often created via aggregating many data sources corresponding to different sub-populations. Each sub-population might exhibit some unique features not shared by others. In classical settings where the sample size is small or moderate, data points from small sub-populations are generally categorized as “outliers” and it is hard to systematically model them due to insufficient observations. However, in the Big data era, the large sample size enables us to better understand heterogeneity, shedding lights toward studies such as exploring the association between certain covariates (e.g., genes or SNPs) and rare outcomes (e.g., rare diseases or diseases in small populations) and understanding why certain treatments (e.g. chemotherapy) benefit a subpopulation and harm another subpopulation. In short, the main advantage brought by Big Data is to understand heterogeneity of sub-populations such as the benefits of certain personalized treatments, which are infeasible when sample size is small or moderate.

Scalability

The processor technology has changed in recent years. The clock speeds have largely stalled and processors are being built with more number of cores instead. Previously data processing systems had to worry about parallelism across nodes in a cluster but now the concern has shifted to parallelism within a single node. In past the techniques which were used to do parallel data processing across data nodes aren't capable of handling intra-node parallelism. This is because of the fact that many more hardware resources such as cache and processor memory channels are shared across a core in a single node.

The scalability issue of Big data has lead towards cloud computing, which now aggregates multiple disparate workloads with varying performance goals into very large clusters. This requires a high level of sharing of resources which is expensive and also brings with it various challenges like how to run and execute various jobs so that we can meet the goal of each workload cost effectively. It also requires dealing with the system failures in an efficient manner which occurs more frequently if operating on large clusters. These factors combined put the concern on how to express the programs, even complex machine learning tasks. There has been a huge shift in the technologies being used. Hard Disk Drives (HDD) are being replaced by the solid state Drives and Phase Change technology which are not having

the same performance between sequential and random data transfer. Thus what kind of storage devices are to be used is again a big question for data storage.

Storage and Processing Issues

The storage available is not enough for storing the large amount of data which is being produced by almost everything: Social Media sites are themselves a great contributor along with the sensor devices etc. Because of the rigorous demands of the Big data on networks, storage and servers outsourcing the data to cloud may seem an option. Uploading this large amount of data in cloud doesn't solve the problem. Since Big data insights require getting all the data collected and then linking it in a way to extract important information. Terabytes of data will take large amount of time to get uploaded in cloud and moreover this data is changing so rapidly which will make this data hard to be uploaded in real time. At the same time, the cloud's distributed nature is also problematic for Big data analysis. Thus the cloud issues with Big Data can be categorized into Capacity and Performance issues.

The transportation of data from storage point to processing point can be avoided in two ways. One is to process in the storage place only and results can be transferred or transport only that data to computation which is important. But both these methods would require integrity and provenance of data to be maintained. Processing of such large amount of data also takes large amount of time. To find suitable elements whole of data Set needs to be Scanned which is somewhat not possible. Thus Building up indexes right in the beginning while collecting and storing the data is a good practice and reduces processing time considerably.

Noise Accumulation

Analyzing Big Data requires us to simultaneously estimate or test many parameters. These estimate errors accumulate when a decision or prediction rule depends on a large number of such parameters. Such a noise accumulation effect is especially severe in high dimensions and may even dominate the true signals. It is usually handled by the sparsity assumption (Donoho, 2000; Hastie et al., 2009; Buhlmann and van der Geer, 2011). Take high-dimensional classification for instance. Poor classification is due to the existence of many weak features that do not contribute to the reduction of classification error (Fan and Fan, 2008). In other words, variable selection plays a pivotal role in overcoming noise accumulation in classification and regression prediction. However, variable selection in high dimensions is challenging due to spurious correlation, incidental endogeneity, heterogeneity, and measurement errors.

Spurious Correlation

High dimensionality also brings spurious correlation, referring to the fact that many uncorrelated random variables may have high sample correlations in high dimensions. Spurious correlation may cause false scientific discoveries and wrong statistical inferences. Besides variable selection, spurious correlation may also lead to wrong statistical inference.

Incidental Endogeneity

Incidental endogeneity is another subtle issue raised by high dimensionality. Unlike spurious correlation, incidental endogeneity refers to the genuine existence of correlations between variables unintentionally,

both due to high-dimensionality. The former is analogous to find two persons look alike but have no genetic relation, whereas the latter is similar to bumping into an acquaintance, both easily occurring in a big city. More generally, endogeneity happens as a result of selection biases, measurement errors, and omitted variables.

Data Access and Sharing of Information

If data is to be used to make accurate decisions in time it becomes necessary that it should be available in accurate, complete and timely manner. This makes the Data management and governance process bit complex adding the necessity to make Data open and make it available to government agencies in standardized manner with standardized APIs, metadata and formats thus leading to better decision making, business intelligence and productivity improvements. Expecting sharing of data between companies is awkward because of the need to get an edge in business. Sharing data about their clients and operations threatens the culture of secrecy and competitiveness.

Quality of Data

Collection of huge amount of data and its storage comes at a cost. More data if used for decision making or for predictive analysis in business will definitely lead to better results. Business Leaders will always want more and more data storage whereas the IT Leaders will take all technical aspects in mind before storing all the data. Big data basically focuses on quality data storage rather than having very large irrelevant data so that better results and conclusions can be drawn. This further leads to various questions like how it can be ensured that which data is relevant, how much data would be enough for decision making and whether the stored data is accurate or not to draw conclusions from it etc.

COMPLEXITY

Fault Tolerance

With the incoming of new technologies like Cloud computing and Big data it is always intended that whenever the failure occurs the damage done should be within acceptable threshold rather than beginning the whole task from the scratch. Fault-tolerant computing is extremely hard, involving intricate algorithms. It is simply not possible to devise absolutely foolproof, 100% reliable fault tolerant machines or software. Thus the main task is to reduce the probability of failure to an “acceptable” level. Unfortunately, the more this probability is reduced, the higher the cost.

Two methods which seem to increase the fault tolerance in Big data are as: First is to divide the whole computation being done into tasks and assign these tasks to different nodes for computation. One node is assigned the work of observing that these nodes are working properly. If something happens that particular task is restarted.

But sometimes it's quite possible that the whole computation can't be divided into such independent tasks. There could be some tasks which might be recursive in nature and the input of the previous task is the input to the next computation. Thus restarting the whole computation becomes cumbersome process. This can be avoided by applying Checkpoints which keeps the state of the system at certain intervals of the time. In case of any failure, the computation can restart from last checkpoint maintained.

Speed/Velocity

For big data, speed/velocity really matters. The capability of fast accessing and mining big data is not just a subjective desire, it is an obligation especially for data streams (a common format of big data) – a processing/mining task must be finished within a certain period of time, otherwise, the processing/mining results becomes less valuable or even worthless. Exemplary applications with real-time requests include earthquake prediction, stock market prediction and agent-based autonomous exchange (buying/selling) systems. Speed is also relevant to scalability – conquering or partially solving anyone helps the other one. The speed of data mining depends on two major factors: data access time (determined mainly by the underlying data system) and, of course, the efficiency of the mining algorithms themselves. Exploitation of advanced indexing schemes is the key to the speed issue.

An additional approach to boost the speed of big data access and mining is through maximally identifying and exploiting the potential parallelism in the access and mining algorithms. The elasticity and parallelism support of cloud computing are the most promising facilities for boosting the performance and scalability of big data mining systems. It is interesting to note that the MapReduce parallel computing model is applicable to only a rather limited class of data-intensive computing problems. Therefore, design of new and more efficient parallel computing models besides MapReduce is greatly desired, but calls for really creative minds.

Accuracy

Data analysis is typically buoyed by relatively accurate data obtained from structured databases with limited sources. Therefore, such analysis results are accurate. However, analysis is adversely affected by the increase in the amount of and the variety in data sources with data volume (Che et al., 2013). In data stream scenarios, high-speed data strongly constrain processing algorithms spatially and temporally. Hence, stream-specific requirements must be fulfilled to process these data (Bifet et al., 2010).

Privacy and Security

It is the most important issue with big data which is sensitive and includes conceptual, technical as well as legal significance.

- The personal information of a person when combined with external large data sets leads to the inference of new facts about that person and it's possible that these kinds of facts about the person are secretive and the person might not want the Data Owner to know or any person to know about them.
- Information regarding the users (people) is collected and used in order to add value to the business of the organization. This is done by creating insights in their lives which they are unaware of.
- Another important consequence arising would be Social stratification where a literate person would be taking advantages of the Big data predictive analysis and on the other hand underprivileged will be easily identified and treated worse.
- Big Data used by law enforcement will increase the chances of certain tagged people to suffer from adverse consequences without the ability to fight back or even having knowledge that they are being discriminated.

Garbage Mining

In the big data epoch, the amount of data produced and inhabited on the World Wide Web keeps increasing at an amazingly fast pace. In such an environment, data can quickly become obsolete, contaminated, and inadequate. In addition, there are data created as junks like junk emails. For having a relatively clean cyberspace and clean World Wide Web, attentions and research efforts are required. Cyberspace cleaning is not an easy task because of at least two foreseeable reasons: garbage is hidden, and there is an ownership issue. Garbage mining is a serious research topic, different but related to big data mining – for the sake the sustainability of our digital environment, “mining for garbage” (and cleaning it) is as important as “mining for knowledge” (the canonical sense of data mining). This is especially so in the new era of big data. Garbage definition remains one of the greatest challenges

Timeliness

With size comes the issue of speed. With increasing volume of data the time to analyze the data will also increase. The design of a system that effectively deals with size is likely also to result in a system that can process a given size of data faster.

Human Collaboration

In spite of the tremendous advances made in computational analysis, there remain many patterns that humans can easily detect but computer algorithms have a hard time finding. Ideally, analytics for Big Data will not be all computational rather it will be designed explicitly to have a human in the loop. The new sub-field of visual analytics is attempting to do this, at least with respect to the modelling and analysis phase in the pipeline. In today’s complex world, it often takes multiple experts from different domains to really understand what is going on. A Big Data analysis system must support input from multiple human experts, and shared exploration of results. These multiple experts may be separated in space and time when it is too expensive to assemble an entire team together in one room. The data system has to accept this distributed expert input, and support their collaboration (Harshawardhan et al., 2014).

FUTURE RESEARCH DIRECTIONS

The amount of data collected from various applications all over the world across a wide variety of fields today is expected to double every two years. It has no utility unless these are analyzed to get useful information. This necessitates the development of techniques which can be used to facilitate big data analysis. The development of powerful computers is a boon to implement these techniques leading to automated systems. The transformation of data into knowledge is by no means an easy task for high performance large-scale data processing, including exploiting parallelism of current and upcoming computer architectures for data mining. Moreover, these data may involve uncertainty in many different forms. Many different models like fuzzy sets, rough sets, soft sets, neural networks, their generalizations and hybrid models obtained by combining two or more of these models have been found to be fruitful in representing data. These models are also very much fruitful for analysis. More often than not, big data are reduced to include only the important characteristics necessary from a particular study point of view or depending upon the application area. So, reduction techniques have been developed. Often

the data collected have missing values. These values need to be generated or the tuples having these missing values are eliminated from the data set before analysis. More importantly, these new challenges may comprise, sometimes even deteriorate, the performance, efficiency and scalability of the dedicated data intensive computing systems. The later approach sometimes leads to loss of information and hence not preferred. This brings up many research issues in the industry and research community in forms of capturing and accessing data effectively. In addition, fast processing while achieving high performance and high throughput, and storing it efficiently for future use is another issue. Further, programming for big data analysis is an important challenging issue. Expressing data access requirements of applications and designing programming language abstractions to exploit parallelism are an immediate need (Acharjya et al., 2015). Additionally, machine learning concepts and tools are gaining popularity among researchers to facilitate meaningful results from these concepts. Research in the area of machine learning for big data has focused on data processing, algorithm implementation, and optimization. Many of the machine learning tools for big data are started recently needs drastic change to adopt it. More efficient tools can be developed for dealing with problems inherent to big data depending upon the advantages and limitations of each tool. The efficient tools to be developed must have provision to handle noisy and imbalance data, uncertainty and inconsistency, and missing values.

CONCLUSION

This chapter provides an overview of challenges in big data analysis. The goals of big data mining techniques go beyond fetching the requested information or even uncovering some hidden relationships and patterns between numeral parameters. Analyzing fast and massive stream data may lead to new valuable insights and theoretical concepts (Berkovich, S., Liao, D., 2012). Comparing with the results derived from mining the conventional datasets, unveiling the huge volume of interconnected heterogeneous big data has the potential to maximize our knowledge and insights in the target domain. However, this brings a series of new challenges to the research community. From a security perspective, the major concerns of Big Data are privacy, integrity, availability, and confidentiality with respect to outsourced data. Large amounts of data are stored in cloud platforms. However, customers cannot physically check the outsourced data. Thus, data integrity is jeopardized. Given the lack of data support caused by remote access and the lack of information regarding internal storage, integrity assessment is difficult. Big Data involves large systems, profits, and challenges. Therefore, additional research is necessary to improve the efficiency of integrity evaluation online, as well as the display, analysis, and storage of Big Data.

KEY TERMS AND DEFINITIONS

Big Data: Big data hold great promises for discovering subtle population patterns and heterogeneities that are not possible with small-scale data.

Big Data Problems: Big data problems such as heterogeneity, noise accumulation, spurious correlations, and incidental endogeneity, in addition to balancing the statistical accuracy and computational efficiency.

Heterogeneity: Big data are often created via aggregating many data sources corresponding to different sub-populations.

Incidental Endogeneity: Incidental endogeneity is another subtle issue raised by high dimensionality.

Noise Accumulation: Analyzing Big Data requires us to simultaneously estimate or test many parameters. These estimate errors accumulate when a decision or prediction rule depends on a large number of such parameters.

Scalability: The scalability issue of big data has led towards cloud computing, which now aggregates multiple disparate workloads with varying performance goals into very large clusters.

Spurious Correlation: High dimensionality also brings spurious correlation, referring to the fact that many uncorrelated random variables may have high sample correlations in high dimensions.

Big Data Analytics and IoT in Smart City Applications

INTRODUCTION

There are many Real Time Applications of Big Data Analytics in Smart City based systems, that incorporates Smart City idea, big data innovations, ongoing big data analytics, urban improvement, data and correspondence innovation, Internet of Things. Technological insurgency in the ongoing past has empowered the idea of Smart City for urban advancement. Smart City idea is imagined with the destinations of giving better administrations to the residents and improves the personal satisfaction. Data and Communication Technology (ICT) and Internet of Things (IoT) made smart city applications as a lot less difficult and compelling. Big data advances assume a significant job in smart city applications. This examination work gives an outline of the job of big data in structure smart city applications and proposes a system for continuous big data analytics. Constant big data analytics help in settling on better choices and progressively precise forecasts at opportune time to offer better administrations to the residents. Here, we focus on some of significant arrangements and administrations for the smart city where the continuous big data analytics and IoT helps in improving the nature of administrations in smart city applications.

There are learning models developed quality education in smart urban communities, that incorporates long transient memory systems, IoT smart city data examination, data and correspondence advancements, sustainable urban life, IoT based administrations, IoT data forecast, Internet of Things idea, profound learning strategies, profound learning methods, IoT based smart city applications, city partners, air quality expectation, profound learning model, smart city forecast problems. In ongoing years, Internet of Things (IoT) idea has turned into a promising exploration point in numerous zones including industry, trade and training. Smart urban areas utilize IoT based administrations and applications to make a sustainable urban life. By utilizing data and correspondence advances, IoT empowers smart urban communities to make city partners progressively mindful, intuitive and productive. With the expansion in number of IoT based smart city applications, the measure of data created by these applications is expanded enormously. Governments and city partners play it safe to process these data and anticipate future impacts to guarantee sustainable advancement. In expectation setting, profound learning procedures have been utilized for a few guaging issues in big data. This motivates us to utilize profound learning techniques for forecast of IoT data. Thus, in exploration work by many eminent researchers, novel profound learning models are proposed for breaking down IoT smart city data. The analysts present novel model dependent on Long Short Term Memory (LSTM) systems to foresee future estimations of air quality in a smart city. The assessment consequences of the proposed model are seen as promising and they demonstrate that the model can be utilized in other smart city forecast issues also.

DOI: 10.4018/978-1-7998-3479-3.ch042

Different Computing Platforms for Big Data Analytics in Electric Vehicle Infrastructures have been developed that incorporate data-concentrated investigation, carbon impression, SG mix, figuring stages, dispersed distributed computing, EV joining, smart vehicular applications, omnipresent arrangement, IoT gadgets, smart matrix mix, wise transportation framework, transport situated smart urban areas, Big Data analytics stages, EV rollout, BDA exercises, structural layers, electric vehicle foundations, ITS, TOSC, appropriated edge-haze computing. With the development of consistently developing smart vehicular applications and pervasive sending of IoT gadgets crosswise over various engineering layers of Intelligent Transportation System (ITS), data-escalated examination rises to be a significant test. Without incredible correspondence and computational help, different vehicular applications and administrations will at present remain in the idea stage and can't be tried in the daily life. In this examination work, the specialists think about the instance of Electric Vehicle (EV) to Smart Grid (SG) combination. The EVs are key players for Transport Oriented Smart Cities (TOSC) as they help urban areas to end up greener by lessening discharges and carbon impression. The analysts break down various use-cases in EV to SG combination to demonstrate how Big Data Analytics (BDA) stages can assume an essential job towards effective EV rollout. The analysts at that point present two figuring stages in particular, dispersed distributed computing and edge/haze registering. The scientists featured the distinctive highlights of each towards supporting BDA exercises in EV reconciliation. At long last, the specialists give a detailed outline of chances, patterns, and difficulties of both these processing strategies.

Big data analytics require advances and technical mechanism that can change a lot of organized, unstructured, and semi-organized data into a more reasonable data and metadata design for explanatory procedures. The calculations utilized as a part of these explanatory instruments must find examples, patterns, and relationships over an assortment of time skylines in the data. In the wake of breaking down the data, these instruments envision the discoveries in tables, diagrams, and spatial outlines for proficient decision making. Along these lines, big data investigation is a genuine test for some applications due to data unpredictability and the adaptability of basic calculations that help such procedures. acquiring supportive data from big data investigation is a basic issue that requires adaptable logical calculations and strategies to return all around planned outcomes, though current methods and calculations are wasteful to deal with big data analytics. In this manner, huge framework and extra applications are important to help data parallelism. In addition, data sources, for example, rapid data stream got from various data sources, have diverse configurations, which makes coordinating different hotspots for analytics arrangements basic. Subsequently, the assessment is centered around the execution of current calculations utilized as a part of big data investigation, which isn't rising directly with the fast increment in computational assets.

By and large, when the expression "big data," is coined, people quickly think about enormous data volumes. In case these were the main reason behind medicinal services administrations to get the better approach for taking care of data, they could regulate without, in light of the way that most of them could contain what they have in a solid social database. In 2001, Doug Laney depicted the "3 Vs" of enormous and complex data as "Volume, Velocity and Variety.". While restorative administrations CIOs could benefit by all of the three, the highlight should be on combination. This is an example experienced by human administrations, just as by all endeavors. Figure 1 demonstrates Big data applications in different fields. Beside customary patient data contained in substance, there are various pictures and sounds recorded, from x-shafts and ultrasounds, to Doppler and MRI imaging. A couple of experts particularly need that their talks with patients be recorded for the patient's bit of leeway. This get-together of dissimilar data is generally unstructured and can't be mentioned in the immaculate tables and sections of a social database. This is the spot big databases, as Hadoop, score. In any case, it is one thing to store big data and extremely another to recoup it truly. Data analysts who can design procedures to remove significant data from the non-successive and evidently unpredictable big databases are presently popular.

Figure 1. Applications of Big data Analytics in various fields

Security and Banking	Manufacturing and Production
Communications and Media	Education & Training
Health Care Applications	Energy Sectors and Utilities
Transportations	Home Appliances

These techniques are challenging and hard to solve, however the IT business is beginning to convey activities that make significant data extraction less demanding. There is additionally a move to a half breed database structure, where data is put away in both a social and a “NoSQL” database. Where social insurance elements have handled this obstacle, the outcome is an all encompassing perspective of the patient, which expels a portion of the unpredictability of finding for the medicinal professional and makes life less difficult for the patient. It likewise opens the path for the move to machine-to-machine (M2M) correspondence and the utilization of computerized reasoning to filter through and investigate data transmitted from the sensors gathering it. The future guarantee is examination that will screen well-being more than ever however there are likewise further issues that should be tended to, for example, data protection and security. Figure 2 represents various smart applications in smart city using Internet of Things.

Figure 2. Applications of IoT in Smart City

Applications of IoT in Smart City	
Smart Traffic Management	Smart Industry
Smart Energy and Smart Grid	Smart healthcare
Smart Transportations	Smart Home Appliances

For analysis of major type of business process, Big Data helps in transforming major selling practice by improved techniques and accurate analysis of presented data. As shown in fig.1 some of such process are Banking and Security, Media and communication, Health Care Sector, Manufacturing, Training and Education, Insurance, Transportation, Energy and utilities. Using big data analytics in all these fields improves the quality of the process and results improved output. The Organisation of the paper has been done as follows. The Second section describes the Literature Review. Section 3 presents applications of big data analytics and IoT in smart city and at last Section 4 concludes the chapter.

2. BACKGROUND

This section presents background of the topic with literature study. Manjunatha, B. Annappa (2018) present Real Time Big Data Analytics in Smart City Applications, that incorporates Smart City idea, big data innovations, ongoing big data analytics, urban improvement, data and correspondence innovation, Internet of Things. Technological insurgency in the ongoing past has empowered the idea of Smart City for urban advancement. Smart City idea is imagined with the destinations of giving better administrations to the residents and improves the personal satisfaction. Data and Communication Technology (ICT) and Internet of Things (IoT) made smart city applications as a lot less difficult and compelling. Big data advances assume a significant job in smart city applications. This examination work gives an outline of the job of big data in structure smart city applications and proposes a system for continuous big data analytics. Constant big data analytics help in settling on better choices and progressively precise forecasts at opportune time to offer better administrations to the residents. Here, the analysts talked about some of significant arrangements and administrations for the smart city where the continuous big data analytics helps in improving the nature of administrations in smart city applications.

M. U. Azimayek (2017) present A profound learning model for air quality expectation in smart urban communities, that incorporates LSTM, long transient memory systems, IoT smart city data examination, data and correspondence advancements, sustainable urban life, IoT based administrations, IoT data forecast, Internet of Things idea, profound learning strategies, profound learning methods, IoT based smart city applications, city partners, air quality expectation, profound learning model, smart city forecast problems. In ongoing years, Internet of Things (IoT) idea has turned into a promising exploration point in numerous zones including industry, trade and training. Smart urban areas utilize IoT based administrations and applications to make a sustainable urban life. By utilizing data and correspondence advances, IoT empowers smart urban communities to make city partners progressively mindful, intuitive and productive. With the expansion in number of IoT based smart city applications, the measure of data created by these applications is expanded enormously. Governments and city partners play it safe to process these data and anticipate future impacts to guarantee sustainable advancement. In expectation setting, profound learning procedures have been utilized for a few gauging issues in big data. This motivates us to utilize profound learning techniques for forecast of IoT data. Thus, in this exploration work, a novel profound learning model is proposed for breaking down IoT smart city data. The analysts propose a novel model dependent on Long Short Term Memory (LSTM) systems to foresee future estimations of air quality in a smart city. The assessment consequences of the proposed model are seen as promising and they demonstrate that the model can be utilized in other smart city forecast issues also. Table 1. Illustrates details of literature survey carried out in this research work.

B. Cheng, S. Longo, F. Cirillo, M. Bauer, E. Kovacs (2015) present Building a Big Data Platform for Smart Cities: Experience and Lessons from Santander, that incorporates Big Data stage, Internet of Things, IoT, human exercises, setting mindfulness, framework design, live city data and analytics stage, CiDAP, SmartSantander, smart city data platforms. The Internet of Things (IoT) is currently forming exploration work 's urban areas to make them increasingly associated, helpful, and keen. In any case, this change will profoundly depend on extricated qualities and bits of knowledge from the big data created by research work 's urban areas by means of sensors, gadgets, and human exercises. Many existing examinations and tasks have been done to make research work 's urban communities smart, concentrating more on the most proficient method to send different sensors and gadgets and after that gather data from them. Be that as it may, this is only the initial move towards smart urban areas and following stage will be to utilize the gathered data and empower setting mindfulness and insight into a wide range of uses

and administrations by means of an adaptable big data stage. In this examination work, the scientists present the framework engineering and the significant structure issues of a live City Data and Analytics Platform, in particular CiDAP. All the more critically, the scientists offer research work ‘ s experience and exercises gained from structure this reasonable framework for an enormous scale running smart city proving ground, SmartSantander. Research work ‘ s work gives a significant guide to future Smart City stage planners with the goal that they can anticipate some training issues and allude to research work ‘ s arrangement when building their very own smart city data stages.

M. M. Hussain, M. M. S. Ask, M. S. Alam, M. Krishnamurthy, Q. M. Ali (2018) present Computing Platforms for Big Data Analytics in Electric Vehicle Infrastructures, that incorporates data-concentrated investigation, carbon impression, SG mix, figuring stages, dispersed distributed computing, EV joining, smart vehicular applications, omnipresent arrangement, IoT gadgets, smart matrix mix, wise transportation framework, transport situated smart urban areas, Big Data analytics stages, EV rollout, BDA exercises, structural layers, electric vehicle foundations, ITS, TOSC, appropriated edge-haze computing. With the development of consistently developing smart vehicular applications and pervasive sending of IoT gadgets crosswise over various engineering layers of Intelligent Transportation System (ITS), data-escalated examination rises to be a significant test. Without incredible correspondence and computational help, different vehicular applications and administrations will at present remain in the idea stage and can’t be tried in the daily life. In this examination work, the specialists think about the instance of Electric Vehicle (EV) to Smart Grid (SG) combination. The EVs are key players for Transport Oriented Smart Cities (TOSC) as they help urban areas to end up greener by lessening discharges and carbon impression. The analysts break down various use-cases in EV to SG combination to demonstrate how Big Data Analytics (BDA) stages can assume an essential job towards effective EV rollout. The analysts at that

point present two figuring stages in particular, dispersed distributed computing and edge/haze registering. The scientists featured the distinctive highlights of each towards supporting BDA exercises in EV reconciliation. At long last, the specialists give a detailed outline of chances, patterns, and difficulties of both these processing strategies.

S. A. Shah, D. Z. Seker, M. M. Rathore, S. Hameed, S. Ben Yahia, D. Draheim (2019) present *Towards Disaster Resilient Smart Cities: Can Internet of Things and Big Data Analytics Be the Game Changers?*, that incorporates IoT, big data analytics advancements, BDA innovations, catastrophe the board exercises, smart city motivations, data reaping, data collection, data pre-handling, smart structures, city contamination, cataclysmic events, fiasco strong smart urban areas, Internet of Things, DRSC condition, Hadoop Ecosystem, Spark, traffic test system, Twitter, crisis clearing path. Disasters (characteristic or man-made) can be deadly to human life, nature, and framework. The ongoing headways in the Internet of Things (IoT) and the advancement in big data analytics (BDA) advances have given an open chance to grow exceptionally required debacle versatile smart city conditions. In this exploration work, the specialists propose and talk about the novel reference design and theory of a debacle versatile smart city (DRSC) through the mix of the IoT and BDA advances. The proposed engineering offers a nonexclusive answer for debacle the board exercises in smart city motivations. A mix of the Hadoop Ecosystem and Spark are checked on to build up a productive DRSC condition that supports both ongoing and disconnected investigation. The execution model of nature comprises of data collecting, data total, data pre-handling, and big data analytics and administration stage. An assortment of datasets (i.e., smart structures, city contamination, traffic test system, and twitter) are used for the approval and assessment of the framework to recognize and create alarms for a fire in a structure, contamination level in the city, crisis departure way, and the gathering of data about catastrophic events (i.e., seismic tremors and tidal waves). The assessment of the framework effectiveness is estimated as far as handling time and throughput that shows the exhibition predominance of the proposed engineering. In addition, the key difficulties confronted are distinguished and quickly talked about.

M. R. Bashir, A. Q. Gill (2016) present *Towards an IoT Big Data Analytics Framework: Smart Buildings Systems*, that incorporates IoT Big Data analytics, IBDA structure, smart structure framework, data stockpiling, data analysis. There is a developing enthusiasm for IoT-empowered smart structures. In any case, the capacity and examination of enormous measure of fast continuous smart structure data is a difficult undertaking. There are various contemporary Big Data the board innovations and progressed analytics procedures that can be utilized to manage this test. There is a requirement for a coordinated IoT Big Data Analytics (IBDA) system to fill the examination hole in the Big Data Analytics domain. This exploration work presents one such IBDA structure for the capacity and investigation of constant data produced from IoT sensors conveyed inside the smart structure. The underlying form of the IBDA structure has been created by utilizing Python and the Big Data Cloudera stage. The materialness of the structure is exhibited with the assistance of a situation including the investigation of continuous smart structure data for naturally dealing with the oxygen level, iridescence and smoke/dangerous gases in various pieces of the smart structure. The underlying outcomes demonstrate that the proposed structure is fit for the reason and appears to be valuable for IoT-empowered Big Data Analytics for smart city. Table 1 displays details of literature survey carried out in this research work.

The present expansion and development in the field of Internet of Things (IoT) are giving surprising potential in the course of the novel era of healthcare. The visualization of the healthcare is expansively supported, as it progresses the perfection of life and health of people, including a few health controls. The perpetual increment of the multifaceted IoT devices in health is comprehensively tried by difficulties, for example, controlling the IoT terminal hubs utilized for health observing, continuous information

handling and shrewd choice and occasion administration. Healthcare plan has been proposed by few researchers which are based with examination of vitality collecting for health observing sensors and the acknowledgment of Big Data investigation in healthcare.

In the choice of the most modern decade, there has been an expanding passion for huge information look into, particularly for health administrations applications. The requisition of the distributed computing and the Internet of Things (IoT) worldview in the healthcare field can convey a few chances to therapeutic IT, and specialists trust that it can essentially enhance healthcare administrations and add to its ceaseless and orderly advancement in a major information condition, for example, Industry 4.0 applications. In any case, the expected assets to oversee such information in a cloud-IoT condition are as yet a major test. In like manner, another model is also planned to streamline virtual machines choice (VMs) in cloud-IoT health administrations applications to productively deal with a major measure of information in incorporated industry 4.0. Industry 4.0 applications require to process and examine huge information, which originate from various sources, for example, sensor information, without human mediation. The proposed demonstrate plans to improve the execution of the healthcare frameworks by lessening the partners' demand execution time, streamlining the required stockpiling of patients' huge information and giving an ongoing information recovery component for those applications.

The inclination of universal frameworks is supported by the improvement and dynamic selection of the Internet of Things (IoT) devices and their empowering advancements. IoT has been appeared to have critical potential in high-chance Environment, Health, and Safety (EHS) enterprises. In these businesses, human lives are in question and IoT-based applications are prepared to offer protected, dependable, and effective arrangements because of their capacity to work at a fine granular level and give rich low-level data. Another research audits existing distributed research on IoT-based applications in high-hazard EHS businesses with particular prominence on healthcare industry, nourishment inventory network (FSC), mining and vitality enterprises (oil and gas and atomic), insightful transportation (e.g., associated vehicles), and building and foundation administration for crisis reaction tasks until 2016. Web of Things (WoT) offers a consistent stage to interface individuals and items to each other for improving and making our lives simpler. This vision conveys us from form based unified plans to a more circulated condition offering a tremendous measure of utilizations, for example, intelligent wearable devices, smart home, perceptive versatility, and savvy urban areas. Few research talks regarding immaterialness of IoT in healthcare and prescription by displaying an all encompassing design of IoT eHealth biological community. Healthcare is ending up progressively hard to oversee because of inadequate and less compelling healthcare administrations to meet the expanding requests of rising maturing populace with constant ailments. We suggest this requires a progress from the center driven treatment to understanding driven healthcare where every operator, for example, clinic, patient, and administrations are flawlessly associated with each other. This patient-driven IoT eHealth biological community needs a multi-layer design: (1) device, (2) mist figuring and (3) cloud to engage treatment of complex information regarding its assortment, speed, and inertness. This mist driven IoT design is trailed by different case cases of administrations and applications that are actualized on those layers. Those illustrations run from versatile health, helped living, e-drug, inserts, early cautioning frameworks, to populace checking in keen urban communities.

Over the most recent couple of years, the m-healthcare applications in light of Internet of Things (IoT) have given multi-dimensional highlights and ongoing administrations. These applications give a stage to a huge number of individuals to get health refreshes routinely for a healthier way of life. Enlistment of IoT devices in the healthcare condition have renewed numerous highlights of these applications. The huge information created by IoT devices in healthcare space is broke down on the cloud rather than exclusively depending on restricted capacity and calculation assets of handheld devices.

In respect to this unique situation, a cloud-driven IoT based M-healthcare checking illness diagnosing system is proposed which predicts the potential ailment with its level of seriousness. Key wordings are characterized to produce client situated health estimations by investigating the idea of computational sciences. The structural model for brilliant understudy healthcare is intended for application situation. The outcomes are registered subsequent to preparing the health estimations in a particular setting. In few research, deliberate understudy point of view health information is created utilizing UCI dataset and medicinal sensors to anticipate the understudy with various illness seriousness. Finding plans are connected utilizing different best in class order calculations and the outcomes are registered in light of precision, affectability, specificity, and F-measure. Exploratory outcomes demonstrate that the proposed technique beats the benchmark strategies for illness forecast.

3. BIG DATA ANALYTICS AND IOT IN SMART CITY APPLICATIONS

One of the biggest obstacles obstructing to utilize big data in social insurance is the manner by which restorative data is spread crosswise over numerous sources represented by various states, clinics, and authoritative offices. Combination of these data sources would require building up another foundation where all data suppliers team up with each other. Similarly critical is actualizing new data examination instruments and procedures. Social insurance needs to get up to speed with different ventures that have effectively moved from standard relapse based techniques to more future-arranged like prescient investigation, machine learning, and chart examination. Table 2 displays details of major contributions performed on applications of big data analytics and IoT in smart city applications.

Big data analytics considers the progression of a wide variety of uses. Things can be looked for, directed, analyzed, and even consolidated into aggregate beguilements. Ventures, human services, and urban regions are abusing IoT data driven frameworks to make these affiliations increasingly beneficial, along these lines, upgrading the lives of occupants. For making IoT a reality, data made by sensors, propelled cell phones, watches, and various wearables ought to be facilitated; furthermore, the significance of IoT data should be explicitly addressed. In any case, the Big Data nature of IoT data powers difficulties that ought to be tended to keeping in consideration the ultimate objective to give flexible and profitable IoT data driven establishments. These issues have been dealt with and focussed on the issues of depicting the centrality of IoT spilling data using reasoning and fusing this data in a learning outline.

The Internet-of-Things (IoT) has supposed control over the business range, and its applications fluctuate broadly from farming and social insurance to transportation. A hospital condition can be extremely upsetting, particularly for senior people and youngsters. With the consistently expanding total populace, the regular patient-physical check up has lost its viability. Thus, keen medicinal services turns out to be critical. Savvy social insurance can be actualized at all levels, beginning from temperature checking for children to following essential signs in the elderly. Data technology has progressed amid the most recent five decades to the phase where its effect is being felt by the general public in each administration that it gets from media, business, health care, shopper devices, vitality and power, and transportation domains. Amid this course of human-technology collaboration tremendous measure of data and learning exchange happens straightforwardly between specialist co-ops and their customers, and in addition by implication between customers. Since human propensity is to “investigate” its past with a specific end goal to foresee the “future”, monitoring this powerfully gushing voluminous heterogeneous data, called Big Data (BD), and examining it for significant revelation of learning that prompts esteem included business turns into a critical research action. It is in this setting research in Big Data (BD) figuring has

developed. Important choices can be construct just with respect to huge information disclosure, which thus requires a decent comprehension of the attributes of the aggregated data, a fitting grouping of this enormous gathering, and a proficient investigation of it. Health care part is a basic framework since its administrations influence the lives of humans and the absence of administration coherence might be unfortunate to the economy and human lives. The huge measure of data gathered by this part from its customers is organized into sections based on importance and relevance and further processed through intelligent utilities.

4. FUTURE RESEARCH DIRECTIONS

Big data analytics and IoT are becoming the research focal point in industries and academia. Data science aims at researching big data and knowledge extraction from data. Applications of big data and data science include information science, uncertainty modeling, uncertain data analysis, machine learning, statistical learning, pattern recognition, data warehousing, and signal processing. Effective integration of

technologies and analysis will result in predicting the future drift of events. Main focus of this section is to discuss open research issues in big data analytics. The research issues pertaining to big data analysis are classified into three broad categories namely internet of things (IoT), cloud computing, bio inspired computing, and quantum computing. However it is not limited to these issues.

Big Data and IoT in Mobile Communication

Internet has restructured global interrelations, the art of businesses, cultural revolutions and an unbelievable number of personal characteristics. Currently, machines are getting in on the act to control innumerable autonomous gadgets via internet and create Internet of Things (IoT). Thus, appliances are becoming the user of the internet, just like humans with the web browsers. Internet of Things is attracting the attention of recent researchers for its most promising opportunities and challenges. It has an imperative economic and societal impact for the future construction of information, network and communication technology. The new regulation of future will be eventually, everything will be connected and intelligently controlled. The concept of IoT is becoming more pertinent to the realistic world due to the development of mobile devices, embedded and ubiquitous communication technologies, cloud computing, and data analytics. Moreover, IoT presents challenges in combinations of volume, velocity and variety. In a broader sense, just like the internet, Internet of Things enables the devices to exist in a myriad of places and facilitates applications ranging from trivial to the crucial. Conversely, it is still mystifying to understand IoT well, including definitions, content and differences from other similar concepts. Several diversified technologies such as computational intelligence, and big-data can be incorporated together to improve the data management and knowledge discovery of large scale automation applications. Much research in this direction has been carried out by eminent researchers.

Big Data and IoT in Cloud Computing

The development of virtualization technologies have made super computing more accessible and affordable. Computing infrastructures that are hidden in virtualization software make systems to behave like a true computer, but with the flexibility of specification details such as number of processors, disk space, memory, and operating system. The use of these virtual computers is known as cloud computing which has been one of the most robust big data technique. Big Data and cloud computing technologies are developed with the importance of developing a salable and on demand availability of resources and data. Cloud computing harmonize massive data by on- demand access to configurable computing resources through virtualization techniques. The benefits of utilizing the Cloud computing include offering resources when there is a demand and pay only for the resources which is needed to develop the product. Simultaneously, it improves availability and cost reduction. Open challenges and research issues of big data and cloud computing are discussed in detail by many researchers which highlights the challenges in data management, data variety and velocity, data storage, data processing, and resource management. So Cloud computing helps in developing a business model for all varieties of applications with infrastructure and tools.

Evolutionary Computing and Big Data Analytics

Bio-inspired computing is a technique inspired by nature to address complex real world problems. Biological systems are self organized without a central control. A bio-inspired cost minimization mechanism

search and find the optimal data service solution on considering cost of data management and service maintenance. These techniques are developed by biological molecules such as DNA and proteins to conduct computational calculations involving storing, retrieving, and processing of data. A significant feature of such computing is that it integrates biologically derived materials to perform computational functions and receive intelligent performance. These systems are more suitable for big data applications.

Big Data Analysis in IoT and Quantum Computing Research

A quantum computer has memory that is exponentially larger than its physical size and can manipulate an exponential set of inputs simultaneously [33]. This exponential improvement in computer systems might be possible. If a real quantum computer is available now, it could have solved problems that are exceptionally difficult on recent computers, of course today's big data problems. The main technical difficulty in building quantum computer could soon be possible. Quantum computing provides a way to merge the quantum mechanics to process the information. In traditional computer, information is presented by long strings of bits which encode either a zero or a one. On the other hand a quantum computer uses quantum bits or qubits. The difference between qubit and bit is that, a qubit is a quantum system that encodes the zero and the one into two distinguishable quantum states. Therefore, it can be capitalized on the phenomena of superposition and entanglement. It is because qubits behave in quantum way. For example, 100 qubits in quantum systems require 2100 complex values to be stored in a classic computer system. It means that many big data problems can be solved much faster by larger scale quantum computers compared with classical computers. Hence it is a challenge for this generation to build a quantum computer and facilitate quantum computing to solve big data problems.

5. CONCLUSION

Big data analytics empowers data diggers and researchers to examine an extensive volume of data that may not be outfit utilizing customary apparatuses. Big data analytics require advances and statistical instruments that can change a lot of organized, unstructured, and semi-organized data into a more reasonable data and metadata design for explanatory procedures. There is tremendous positive potential concerning application of big data in smart city applications. The above chapter focuses on many versatile applications related to smart city and the contribution of big data analytics in IoT based systems to enhance the functionality of intelligent IoT systems.

KEY TERMS AND DEFINITIONS

Big Data: Big data frequently refers to data sets with sizes away from the ability of frequently used software tools to confine, curate, administer, and process data contained by a supportable elapsed in-

stance. Big data philosophy encompasses shapeless, semi-structured and prepared data, however the main focal point is on unstructured data.

Big Data Analytics: Big data analytics is the often composite process of examining large and wide-ranging data sets, or big data, to come across information—such as concealed patterns, indefinite correlations, market development and client preferences—that can help organizations create informed business decisions.

Cloud Computing: Cloud computing is the on-demand ease of use of computer system resources, particularly data storage and computing influence, without direct active organization by the user. The expression is generally used to explain data centers obtainable to many users over the Internet.

Evolutionary Computing: In computer science, evolutionary computation is a ancestors of algorithms for comprehensive optimization inspired by biological evolution, and a coordinated section of artificial intelligence and soft computing using these algorithms.

Internet of Things: The Internet of Things (IoT) is a arrangement of organized computing devices such as mechanical equipment or digital machines, they can be objects or community that are provided with exclusive identifiers and the facility to transfer data over a set-up without requiring human-to-human or human-to-computer communication.

Mobile Communication: Mobile communication allows broadcast of voice and multimedia data via a workstation or a mobile device exclusive of having connected to any physical or fixed connection. Mobile communication is growing day by day and has become a must have for every person. Mobile communication is the exchange of voice and data using a communication facility at the same time without any physical link.

Quantum Computing: All computing systems rely on an elementary ability to store and control information. Existing computers manipulate individual bits, which accumulate information as binary 0 and 1 states. Quantum computers focus more power on quantum mechanical phenomena to direct required information.

Data Streaming Processing Window Joined With Graphics Processing Units (GPUs)

Shen Lu

University of South Florida, USA

Richard S. Segall

Arkansas State University, USA

INTRODUCTION

A massive wave of changes in industries are created by data. Business models, applications and even data driven economy depend on data to overcome the stress of the competition and even ensure the certainty of the survival. Data can represent not only the development trends but also the values of the changes. With the time passing, the values of data decreases, which makes the usage of time-series time more important.

Big Data is Large-scale data and can be either discrete or continuous. This article entails research that discusses the continuous case of Big Data often called “Data Streaming”. More and more businesses will depend on being able to process and make decisions on streams of data. This article utilizes the algorithmic side of data stream processing often called “stream analytics” or “stream mining”.

In a streaming data system, the data is made available at the moment a client application needs it. As stated by Warski (2016) processing data in a streaming fashion has become more and more popular over the “traditional” way of batch processing of Big Data sets available as a whole. According to Warski (2016), the focus has shifted in the industry of “it’s no longer that important how big is your data but rather it’s much more important of how fast you can analyze it and gain insights.”

Data stream processing incorporates a notion of a Window on a stream as a way to convert an infinite stream into a finite relation in order to apply relational operations. The data stream can be based on either time or the tuple. Time-based execution provides a way to model simultaneity, and tuple-based execution provides a way to react to primitive events. To process the two different kinds of streams, one would need to find a convergence language in which the simple difference between the two streams would be resolved. For this data streaming Window Join, one would need to focus on time-based data stream.

BACKGROUND

A Central Processing Unit (CPU) is the electronic circuitry within a computer that carries out the instructions of a computer program by performing the basic arithmetic, logical, control and input/output (I/O) operations specified by the instructions. The computer industry has used the term “central processing unit” at least since the early 1960s. Traditionally, the term “CPU” refers to a processor, more specifically to its processing unit and Control Unit (CU), distinguishing these core elements of a computer from external components such as main memory and I/O circuitry. (Wikipedia (2018e)).

DOI: 10.4018/978-1-7998-3479-3.ch043

A Graphics Processing Unit (GPU) is a specialized electronic circuit designed to rapidly manipulate and alter memory to accelerate the creation of images in a frame buffer intended for output to a display device. GPUs are used in embedded systems, mobile phones, personal computers, workstations, and game consoles. Modern GPUs are very efficient at manipulating computer graphics and image processing, and their highly parallel structure makes them more efficient than general-purpose CPUs for algorithms where the processing of large blocks of data is done in parallel. In a personal computer, a GPU can be present on a video card, or it can be embedded on the motherboard or—in certain CPUs—on the CPU die. (Wikipedia (2018d)).

Figure 1 below shows the highlights of comparisons between Central Processing Unit (CPU) versus Graphics Processing Unit (GPU). Note that a CPU has a low compute density and a GPU has a high compute density. A CPU has a low latency tolerance and a GPU has a high latency tolerance, where latency refers to a measure of the time delay required for information to travel across a network. A CPU has shallow pipelines in contrast to a GPU that has high throughput. Hence this article discusses experiments using GPUs that are extremely more efficient than the traditional CPU framework.

Figure 1. Comparison of CPU (Central Processing Unit) vs. GPU (Graphics Processor Units (GPUs))

Below is a table of highlights of research advances from 2002 to 2018 in data streaming related to the data streaming processing of Window Joins with Graphics Processing Units (GPUs) and topic of processing algorithms for data analysis of streaming data.

Table 1. Highlights of Research Advances in Data Streaming (2018-2002)

2018

Akidau et al. (2018) presents and discusses many figures for pattern analysis for data streaming and windowing strategies (See Figure 2 below) including that for variations for fixed windows, sliding windows, and sessions. Akidau et al. (2018) also discusses event-time windowing and processing-time windows using triggers and ingress times.

Aragues (2018) discusses in-depth chapters on processing streaming data for visualization and streaming visualization techniques, and also how to show machine learning results (such as scores or classifications) as data is classified in a streaming workflow. Aragues (2018) also states that visualizations can help us understand security using the relationships between and timelines of various threats, as security data often requires secondary lookups for history and context that can also be shown in a streaming visualization.

Bifet et al. (2018) is another book on subject of machine learning for data streams with practical examples in Massive Online Analysis (MOA) that includes discussions mining of streams using (1.) frequent pattern, (2.) frequent itemset and (3.) frequent subgraph.

2017

Basak et al. (2017) discusses stream analytics with Microsoft Azure and also the JOIN command for integrating streaming data that requires the data sources to be temporally constrained. Azure Stream Analytics is a fully managed cost effective real-time event-processing engine that helps to unlock deep insights from data. Stream Analytics makes it easy to set up real-time analytic computations on data streaming from devices, sensors, web sites, social media, applications, infrastructure systems, and more. Basak et al. (2017) also discusses windowing for tumbling windows, hopping windows, and sliding windows.

Psaltis (2017) wrote an entire book on understanding the real-time pipeline of streaming data. Psaltis (2017) contains an entire chapter on algorithms for data analysis of streaming data including sliding window and tumbling window techniques and their support in popular stream-processing frameworks.

Familiar and Barnes (2017) discusses in depth real-time processing using Azure Storm Analytics using SQL query dialect features, and also security and identity authorization and authentication using threat modeling zones and IoT (Internet of Things).

2016

Dunning and Friedman (2016) authored a book on streaming architecture with new designs using Apache Kafka and MapR streams that included topics of fraud detection with streaming data and geo-distributed data streams. As Dunning and Friedman (2016) indicate MapR Streams has many differences with Apache Kafka that include running a much larger number of topics and applying policies such as time-to-live or controlled access to many topics as a group. The ability to set up a very large number of topics in MapR Streams lets the building of topics that reflect business goals rather than infrastructural limitations.

As Dunning and Friedman (2016) state: each MapR stream can contain hundreds of thousands or more topics and partitions, and each MapR cluster can have millions of streams. In comparison, an Apache Kafka cluster consisting of server processor called “brokers” each of which should not have more than a thousand partitions per broker.

Galic (2016) is a book on spatio-temporal data streams that discusses time-based windows, tuple-based windows, and predicate-based windows, and data stream clustering.

Garofalakis et al. (2016) edited a book on data stream management that includes individual chapters on topics on foundations and basic stream synopses such as data-stream sampling, distinct-values estimations over data streams, and the sliding-window computation model and results.

2015

Dallachiesa et al. (2015) studied uncertain data streams by showing how current-state-of-art techniques for answering similarity join techniques can be easily adopted to be used with these under a variety of configurations using real data. Dallachiesa et al. (2015) showed that their algorithms used to maintain uncertain sliding windows can efficiently operate while providing a high quality approximation in query answering. Dallachiesa et al. (2015) also showed that sort-based similarity join algorithms can perform better than index-based techniques when the number of possible values per tuple is low as in many real-world applications.

According to Pinnecke et al. (2015) stated that the need of continuous processing and analysis of data streams has increased rapidly and that very large windows cannot be passed directly to the GPU and proposed to split the variable-length windows into fixed sized windows. Pinnecke et al. (2015) presented

a time and space efficient, data-corruption flow concept for this task and identified open research challenges related to co-processing in the context of data stream processing.

2014

Ellis (2014) wrote a book on real-time analytics as techniques to analyze and visualize streaming data that including sampling from a streaming population such as “sliding window reservoir sampling”.

2013

Kim & Kim (2013) provided a review of Window query processing for data streams that includes discussions of query plan structure, blocking operators, operator scheduling, load shedding and disorder control. Load shedding algorithms for Window joins can be classified into frequency-based model, age-based model, and pattern-based model. A data stream is an ordered sequence of data items, and the order is important in windowing data streams.

2011

Deshpande (2011) wrote a book on designing and managing a powerful data replication solution for the software product of ORACLE Streams 11g that depicts the Streams information flow as consisting of the three stages of: capture, staging and propagation, and consumption.

2010

Bifet (2010) is book that focuses on the design of learning algorithms for evolving and time-changing data streams called “adaptive streaming”. The basic building block in Bifet (2010) is the adaptive sliding algorithm, ADWIN, for change detection and value estimation. Bifet (2010) makes significant contributions to mining time-changing streams.

Gama (2010) discussed knowledge discovery from data streams using thirty-one different algorithms, novelty detection in data streams, and time-series data streams.

2007

Ghanem et al. (2007) proposed the Synchronized SQL (or SyncSQL) query language that defines a stream as a sequence of modify operations (i.e. insert, update, and delete) against relations with a specified schema. As Ghanem et al. (2007) indicated an important issue in continuous queries over data streams is the frequency by which the answer gets refreshed and the conditions that trigger the refresh. Coarser periodic refresh requirements are typically expressed as sliding-window queries.

2006

Sliding window query processing over data streams has been studied by Golab (2006) who developed solutions for efficient query processing over sliding windows of Data Stream Management Systems (DSMS) where there existed opportunities for resource sharing among similar queries because a large number of persistent queries could be executed at the same time.

2005

Previous related work utilizing Graphics Processing Units (GPUs) include that of Govindaraju et al. (2005) who presented algorithms for fast quantile and frequency estimation in large data streams. Govindaraju et al. (2005) used GPU as a co-processor to minimize the data transmission between CPU (Central Processing Unit) and GPU by taking into account the low bus bandwidth with results that demonstrate that the graphics processor available on a commodity computer system is an efficient stream-processor and a useful co-processor for mining data streams.

2003

Hammad et al. (2003) showed how the straightforward application of traditional pipelined query processing techniques to sliding Windows queries could result in inefficient and incorrect behavior. Hammad et al. (2003) presented three alternative execution techniques that guarantee correct behavior for pipelined sliding window queries and develop new algorithms for correctly evaluating Window-based duplicate-elimination, Group-By and Set operations in this context.

2002

Babcock et al. (2002) researched models and issues in data stream systems as models of multiple, continuous, rapid, time varying systems. Babcock et al. (2002) explored topics in stream query languages, new requirements and challenges in query processing, and algorithmic issues.

DATA STREAMING WINDOWS JOIN

Xie and Yang (2007) presented a survey of join processing in data streams. Datastreams.com (2018) discussed different ways of joining streams using Apache Spark 2.3.0 for stream-stream joins in Structured Streaming. Das et al. (2003) considered the problem of approximating sliding window joins over data streams in a data stream processing system with limited resources. Golub and Ozsu (2003) studies processing window multi-joins in continuous queries over data streams.

There are several types of Windowing strategies, and Akidau et al. (2018) illustrate and discuss the three types of (1.) fixed, (2.) sliding, and (3.) sessions as illustrated in the below Figure 2.

Using Graphics Processing Unit (GPU) can improve data streaming Window Joins for higher performance computing. Two independent threads generate data streams: one thread can be used to generate data stream A, and the other thread can be used to generate data stream B.

One would use a Windows Join thread to merge the two data streams, which is also the process of “Data Stream Window Join” as used in the title of this article. The Window Join Process can be implemented in parallel that can efficiently improve the computing speed. Data streams are loaded into multiple-thread GPU (Graphic Processing Unit) card, each data unit is loaded into a thread, and all of the data units can do computing at the same time, which can efficiently improve the throughput.

Because GPU (Graphics Processing Unit) machine has global memory and GPU card as central computing unit to store and process data, one would need special data structures to store data streams, array pointers, and temporary variables.

Figure 2. Windowing Strategies: Each example is shown for three different keys, highlighting the difference between aligned windows and unaligned windows. (Source: Akidau et al. (2018), p.17 and 33).

GPU has multiple-threading feature that makes the computing process different from single thread computing. To take advantage of this feature, one would need to put computing units into as many threads as possible. This article discusses choosing hash-table as the data structure to sort and store data, because, it can make the best use of the multiple-threading feature and efficiently improve the computing performance.

The `cudaMemcpyToSymbol` can be used to copy bytes from the memory area pointed to by source to the memory area pointed to by offset bytes from the start of symbol. The memory areas may not overlap. The symbol can either be a variable that resides in global or constant memory space, or it can be a character string, naming a variable that resides in global or constant memory space. As CUDA Programming Blogspot (2013) indicates, we use “constant memory” for data that will not change over the course of a kernel execution.

The kind can be either `cudaMemcpyHostToDevice` or `cudaMemcpyDeviceToDevice`. We use `cudaMemcpyToSymbol` to assign a global memory space to a circle queue and keep it in global memory as long as the data streams are going from host machine to device. It can be updated when the sliding window moves from time to time. We check the out of day of the time stamp from the front to the end. If the time stamp of the data item is out of date, the data can be deleted. We insert the data to the end of the queue. We need to check if the queue is full or not. Technically, if the GPU computing speed is faster than or equal to the CPU data generating speed, the circle queue cannot get full.

For GPU Data Stream Window Join, there are two steps: one is hash two data streams into two different arrays; the other is merge the two arrays and print the results.

PSEUDOCODE

According to Wikipedia (2018), a Pseudocode is an informal high-level description of the operating principle of a computer program or other algorithm. It uses the structural conventions of a normal programming language, but is intended for human reading rather than machine reading. That is, a Pseudocode is an artificial and informal language that helps programmers develop algorithms.

The “Pseudocode” provided in the Appendix of this article is composed of two threads: one is for consumer, the other is for producer. When the program is loaded, one of the threads is executed continuously without termination. Producer thread is then used to generate data following the use of consumer thread to do Windows Join. Producer function creates two streams. Consumer function is then used on the two streams to build and update the histogram, and generate results.

The use of Graphics Processing Unit (GPU) offers the high throughput of batch processors, the low latency of stream processors, and the ability to perform iterative and incremental computations. High-level programming models can be built on low-level primitives enabling such diverse tasks as streaming data analysis, iterative machine learning, and iterative graph mining.

CUDA® is a parallel computing platform and programming model developed by NVIDIA for general computing on Graphics Processing Units (GPUs). With CUDA, developers are able to dramatically speed up computing applications by harnessing the power of GPUs. For Windows Join on a CUDA machine, there are three steps:

1. Distribute incoming data to the hash table.
2. Update hash table: delete out-of-date entities.
3. Merge two hash tables.

These three steps take advantage of the multiple processors in GPU in order to gain high throughput. Both hash table data structure and the data merge are based on Parallel Computing. Data are distributed on difference threads, each thread can work independently to map to send data to corresponding hash bucket and select data from the other hash table to merge and to generate results. All of the threads can work simultaneously which can ensure the improvement of the throughput twenty to thirty times faster.

EXPERIMENTS

The data streams were generated on multiple-thread single-processor Windows workstation, as shown in Table 2. The Window joins were performed on Linux server with GPU with the machine details as are listed in Table 3.

Table 2. Multiple-thread Single-processor Windows Workstation

	CPU
Architecture	X86_64
Processor	Intel(R) Core(TM) i7-3930K CPU @ 3.20GHz
Core(s) per socket	6
Socket	1
CPU MHz	1200.0
L1i cache	32k
L1d cache	32k
L2 cache	256k
L3 cache	12288k
Linux version	3.11.0-26-generic

Table 3. Linux Server with GPU (Graphics Processing Units)

	GPU
Product	GF110GL
Vendor	NVIDIA
Version	A1
Width	64 bits
Clock	33MHZ
capabilities	vga_controller bus_master cap_list rom
Configuration	Driver=NVIDIA Latency=0

Table 4. Throughput of Data Stream Window Join for different sizes of windows

Window Size (million seconds)	Time Cost (million seconds)
10	418.976
20	385.284
20	533.759
40	612.361
50	669.958
60	742.854
70	907.188
80	1020.676
90	1131.624
100	1254.414

We tested the hash join algorithm on a streaming Window from 10 million seconds to 100 million seconds. With the increase of the size of the streaming window, the throughput increase, as shown in Table 4 and Figure 3. The performance of the hash join on different data sets is shown in Tables 5 and 6 below. An individual thread handles each tuple. All of the data are processed in parallel.

We made two algorithms for Data Stream Window Join for the purpose of comparison: one is based on static data, the other is based on dynamic data. When we use static data to do window join, experimental results are shown in Table 5. The performance of the dynamic Data Stream Window Join is shown in Table 6.

For static Data Stream Window Join, we also measured the time cost of Window Join. For Dynamic Data Stream Window Join, the Window Join can happen any time when producing data stream. We cannot measure how long it took to join data streams. In Figure 3 is the time cost of the hash join on static data. With the increase of the Window size, the time cost is randomly changed. In Figure 4 is the time cost of the hash join on dynamic data. With the increase of the window size, the time cost increases.

As shown in Figure 4, using static data, the time in seconds for hash join in a Window is cyclical with global maximum using Window size of 45 followed with a global minimum using Window size of 50 and local minimum using Window size of 20.

As shown in Figure 5, using dynamic data, the time in seconds taken for hash join monotonically increases with increasing number of tuples in a Window. Using the dynamic data, there is a decrease of

Figure 3. Throughput for Data Stream Window Join

Table 5. Data Stream Window Join with Static Data

Window Size	Number of Tuples in R	Number of Tuples in S	Time taken for Hash Join
10	8214	8517	46.91
15	11011	11438	74.46
20	13165	13623	16.47
25	14847	15320	55.68
30	16224	16693	68.92
35	17344	17802	61.72

Figure 5. Data Stream Window Join with Dynamic Data

number of tuples in a Window when Window size is 25, and a maximum when the Window size is 45 that precedes a substantial decrease when Window size is 50 that precedes a marginal increase.

FUTURE RESEARCH DIRECTIONS

The future research directions are to perform additional experiments using both static and dynamic data of varying dimensionalities with different Graphics Processing Units (GPU) and make corresponding comparisons, as well as investigating the relationship between stream processing and General Purpose GPUs (GPGPU) as discussed below.

With the emergence of deep learning, the importance of GPUs has increased. In research done by Indigo, it was found that while training deep learning neural networks, GPUs can be 250 times faster than CPUs. The explosive growth of Deep Learning in recent years has been attributed to the emergence of General Purpose GPUs. There has been some level of competition in this area with Application-Specific Integrated Circuits (ASIC), most prominently the Tensor Processing Unit (TPU) made by Google. However, these can require changes to existing code and GPUs are still very popular. (Wikipedia (2018d))

Stream Processing and General Purpose GPUs (GPGPU)

It is becoming increasingly common to use a General Purpose Graphics Processing Unit (GPGPU) as a modified form of stream processor (or a vector processor), running compute kernels. This concept turns the massive computational power of a modern graphics accelerator's shader pipeline into general-purpose computing power, as opposed to being hard-wired solely to do graphical operations. In certain applications requiring massive vector operations, this can yield several orders of magnitude higher performance than a conventional CPU. (Wikipedia (2018d)).

The two largest discrete GPU designers, AMD (Advanced Micro Devices, Inc.) and Nvidia, are beginning to pursue this approach with an array of applications. Both Nvidia and AMD have teamed with Stanford University to create a GPU-based client for the Folding@home distributed computing project, for protein folding calculations. In certain circumstances, the GPU calculates forty times faster than the conventional CPUs traditionally used by such applications. (Wikipedia (2018d)).

GPGPU can be used for many types of embarrassingly parallel (Wikipedia (2018f)) tasks including ray tracing. They are generally suited to high-throughput type computations that exhibit data-parallelism to exploit the wide vector width Single Instruction Multiple Data (SIMD) architecture of the GPU.

Furthermore, GPU-based high performance computers are starting to play a significant role in large-scale modelling. According to the Top500 (2012) supercomputers list, three of the 10 most powerful supercomputers in the world took advantage of GPU acceleration.

CONCLUSION

This article compared the differences of Central Processing Units (CPU) versus Graphics Processing Units (GPU), discussed and summarized advances in data streaming and its relationship to data streaming processing of Window Joins with Graphics Processor Units (GPUs), and compared processing of data streaming with experiments performed using a Pseudocode as provided in Appendix.

The comparisons of data stream Window Joins are made with both static and dynamic data. The article illustrates the endless potential of the importance and applicability of data streaming for processing using technology such as Graphics Processing Units.

KEY TERMS AND DEFINITIONS

Adaptive Streaming: Technique used in streaming multimedia over computer networks that works by detecting a user's bandwidth and CPU capacity in real time and adjusting the quality of the media stream accordingly (Wikipedia, 2018a).

ADWIN: Adaptive sliding window algorithm for change detection and value estimation with strong theoretical guarantees (Gama, 2010).

CUDA: Is a parallel computing platform and application programming interface (API) model created by Nvidia. It allows software developers and software engineers to use a CUDA-enabled Graphics Processing Unit (GPU) for general purpose processing – an approach termed GPGPU (General-Purpose computing on Graphics Processing Units; Wikipedia, 2018b).

cudaMemcpyToSymbol: Used to copy bytes from the memory area pointed to by source to the memory area pointed to by offset bytes from the start of symbol.

Data Stream: Continuous unbounded sequence of data values that arrive in time at a port on a system (Govindaraju et al., 2005, p. 613).

Data Stream Management System (DSMS): Database management system (DBMS) adopted to the continuous unbounded sequence of data values that compose data stream (s) (Babcock et al., 2002, p. 1).

Embarrassingly Parallel: Workload or problem (also called perfectly parallel or pleasingly parallel) is one where little or no effort is needed to separate the problem into a number of parallel tasks. This is often the case where there is little or no dependency or need for communication between those parallel tasks, or for results between them (Wikipedia, 2018f).

Graphics Processing Unit (GPU): A specialized computer processor, addresses the demands of real-time high-resolution 3D graphics compute-intensive tasks (Wikipedia, 2018d).

Hash Table (Hash Map): A data structure which implements an associative array abstract data type, a structure that can map keys to values. A hash table uses a hash function to compute an index into an array of buckets or slots, from which the desired value can be found (Wikipedia, 2018c).

Hopping Windows: Group events for aggregation and are windows of equal duration but overlap at regular intervals (Basak et al., 2017, p. 115).

Sliding Windows: Define all possible intervals of equal duration and output aggregations based on actual event stream activity (Basak et al., 2017, p. 116).

Streaming Data System: A non-hard real-time system that makes its data available at the moment a client application needs it (Psaltis, 2017, pp. 8-9).

Streaming Mining: Knowledge discovery from data streams (Gama, 2010).

Tumbling Windows: Intervals defined to group events for aggregation, and are windows that are contiguous and of equal duration (Basak et al., 2017, p. 113).

Windows Join: Integrates two or more inputs or input-derived data sets, just as in SQL (Structured Query Language) but requires the data sources to be temporarily constrained to match the sources for a window of time (Basak et al., 2017, p.111).

INTRODUCTION

Data analysis of a study and its subsequent statistical processing represent the base of numerous research works carried out in any scientific field. The wide variety of techniques allow an in-depth analysis of any data set depending on the desired goal – such goal has to be taken into account at the beginning of the study and it has to assume central importance during the research design, as it requires the verification of a set of hypotheses. The refutation of one or more hypothesis needed for the application of a particular statistical technique may lead to inconsistent or invalid results, which would in turn invalidate the whole research.

The vast majority of techniques applied in research is aimed at inferring the results of a sample to the target population of the study, which at the same time entails a certain degree of uncertainty – this degree of uncertainty can be controllable and measurable as long as the application conditions of the techniques are met. Its refutation may involve from a slight increase of the degree of uncertainty to its immeasurability. It is crucial for the researcher to possess a proper knowledge of the technique so as to obtain the results and the conclusions of his investigation.

However, and due to the great variety of techniques, its misuse in research is very common, either because of the refutation of any of the hypothesis set or because of the nature of the data that is being analysed. Because of that, the results obtained from its application cannot be taken into consideration due to its lack of validity.

Some of the main statistical techniques used in different research fields are presented in this chapter. A brief definition of each technique, together with the specification of its utility is included as well, in order to determine accurately its purpose. The required hypothesis regarding data and regarding experimental design are listed as well. Besides, some of the computer programs with which these techniques can be used are listed – we emphasize in R, a free and open-source software with multiple packages that allow to apply these techniques in an effective and simple way.

DOI: 10.4018/978-1-7998-3479-3.ch044

The analysis of the great amount of statistical techniques that exist would require a much larger extension than that available in this chapter, so the most used ones have been selected. Some of the simplest ones have been included (such as descriptive analysis, graphic analysis or parametric and non-parametric hypothesis testing for statistical inference), as well as some multivariate analysis techniques, such as principal component analysis, factor analysis, structural equation models, regression analysis and causal models.

BACKGROUND

The word *Statistics* comes from the Italian word *Statista*, meaning “Statesman” – referring to its first meaning as a science used by the Government to collect socio-demographic information from its population. From its introduction, it has experimented several extensions in its definition. During the nineteenth century, its field of action was enlarged to the “recollection of information from any data set”, and therefore, its application to other disciplines was extended as well. Later, the analysis and interpretation of data was also considered as a part of the discipline.

However, even though the origin of the word dates from the eighteenth century, Statistics had already been used by the Babylonian and Egyptian civilizations in the elaboration of frequency tables and population censuses. Several authors consider four fundamental periods during the development of Statistics: a period up to 1750 is characterized by the development of probability and the exposition of non-probabilistic methods of data analysis; a period from 1750 to 1820 when inference and mathematical statistics were introduced with works from Laplace and Gauss; a period from 1820 to the early twentieth century with works from Galton, Pearson and Fisher, when statistical inference, correlation and statistical models were developed; and a fourth period, during the last third of the twentieth century, with a strong evolution of Computer Science (Fienberg, 1992). Since then, the amount of techniques developed has been significantly extended due to the calculation capacity of computers.

Therefore, descriptive analysis and the elaboration of representative graphics can be framed within the beginning of Statistics as a discipline, while regression analysis and statistical inference were developed during the nineteenth century, whose most relevant researchers in the field are shown in Figure 1. Other techniques were developed during the twentieth century. And most of those were developed during its second half, after the revolution that took place due to the calculation capacity of computers. Factor analysis was developed by Charles Spearman during 1904 and later on by Louis Leon Thurstone. Due to the evolution of this methodology, together with Biometrics, Econometrics and Computing, structural equation models were born during the 70's. Principal component analysis is due to Hotelling (1933). And by the end of the twentieth century, artificial neural networks started to be applied to numerous statistical problems such as estimation or classification.

This great development has favoured the appearance of a large number of research works that use statistics to obtain important results that permit correct decision-making in important fields such as Health Sciences, Engineering or Social Sciences. Kaplan-Meier estimator, for instance, was developed in 1958 (Kaplan & Meier, 1958) and has been used in Engineering, Medicine and Economy to estimate the survival of the components of a machine, the survival of patients of a certain disease or the time it takes for a person to return to the active market after losing his job.

Each and every one of the existing statistical techniques are based on a mathematical basis that allows to demarcate with exactitude the conditions of applicability of the technique and its degree of uncertainty, if any. The application of a technique under different conditions of those for which it was designed is

Figure 1. Most relevant researchers in Statistics during 19th century

nonsense, although the technique may be applied numerically. To illustrate the previous statement, let X be the variable *Gender* measured for a group of individuals belonging to a certain population that contains the categories x_1 : “Man” and x_2 : “Woman”. The impossibility of calculating the mean of all values is obvious, since its mathematical expression would be:

$$\bar{x} = \frac{x_1 \cdot n_1 + x_2 \cdot n_2}{n_1 + n_2}$$

Where n_1 and n_2 are the number of men and women, respectively, of the study sample. Its categories are not numeric, so the calculation is not possible. On the contrary, the calculation would be possible if numerical values were assigned to each category, for example, 1 to x_1 : “female” and 2 to x_2 : “male”, so the result would be a value comprised between 1 and 2 that, even though it can be calculated numerically, is nonsense (Figure 2).

Figure 2. Example of the arithmetic mean for a dichotomous variable

Only in the case that the values 0 and 1 were assigned to the two modalities, there would be a coincidence between the value of the arithmetic mean and the proportion of individuals that verify modality 1, and therefore its calculation would make sense. In the example of Figure 2, if the value 1 is assigned to female and 0 to male, the arithmetic mean would be:

$$\bar{x} = \frac{1 \cdot 6 + 0 \cdot 9}{15} = 0.4$$

Consequently, the arithmetic mean could be interpreted as the proportion of females in the analysed sample, that is, a 40% of the individuals, and also, a possible estimation of the population portion.

In order to carry out a proper research it is necessary to define, previously, the desired objective and the appropriate statistical techniques that could be applied to achieve such objective. Also, a correct definition of the target population must be made, as an unrealistic consideration of it can generate an important sampling bias. Because of that, it is necessary to be precise (Holmes, 2004).

Once this is done, it is time to start data collection for the subsequent implementation of the techniques. This process can be divided into two main parts: sample selection and the development of data collection instrument. If the study aims for the inference of the results of a sample to its population, it is necessary that - among many other characteristics that can be consulted in Lohr (2009) or Fowler Jr. (2013) - the sample selection process was random and representative of the population for which it was designed.

Besides, this data collection instrument must be valid and consistent with the research objective. The most used data collection instrument is the *opinion questionnaire*, for which the following stages can be established for its elaboration: (1) the type of information needed is clearly defined, as well as the individuals for whom the instrument is being prepared; (2) the type of questions that are to be included (open or closed) are determined and written according to principles of simplicity, clarity and objectivity; (3) an introductory text is written and the instructions for the interviewer and the respondent are elaborated; and (4) the formal design of the questionnaire is included in the final stage of the elaboration of the questionnaire. Once constructed, the reliability and validity of the questionnaire must be analysed, as well as the suitability of the variables obtained through it, so as to verify the proper application of the desired statistical techniques. This can be consulted with greater detail in Blair, Czaja and Blair (2013). Through this instrument the variables describing the available information can be obtained - they must be correctly defined so that their modalities are exclusive. A variable can be qualitative or quantitative depending on the way in which the information is collected. This must be chosen, once more, according to the objective pursued. For example, the variable *Age* can be measured discretely, by intervals or qualitatively by means of a categorization, if the desire is to determine if the individual verifies a condition related to it. As we have discussed previously, the quantitative or qualitative nature of the variable determines the techniques that may be applied later.

When all the information has been collected and subsequently tabulated, the process of verifying hypothesis compliance for the application of the desired statistical techniques starts. Each technique, depending on their mathematical basis, requires the verification of a different set of conditions. Parametric techniques, which have higher power, are more demanding than nonparametric techniques. For this reason, sometimes the latter should be used as an alternative to the former and never be used despite their noncompliance.

After implementing these techniques to the research and obtaining the respective results, the conclusions extracted from them must be coherent so that, when inferring the results to the population, it

matches the one defined at the beginning of the research, and so that the possible existing weaknesses can be perceived and assessed. The lack of accuracy within the statements can result in misinterpretations.

FOCUS OF THE ARTICLE

The necessary information for the correct application of the techniques discussed above is detailed below. It includes a definition of each technique, as well as information regarding their utility, the objective pursued through their application, the hypothesis required and their implementation through computer software – specially R (Version 3.5.1; Ihaka & Gentleman, 2018).

Descriptive Analysis

A variable can be defined as the characteristic which is the object of a statistical study. This characteristic can be of different nature according to the values that it takes. In this way, we can make a simple classification between qualitative and quantitative variables. On the one hand, qualitative variables describe an intrinsic quality of an individual and whose value only identifies it, by characterizing it with respect to others (for instance: gender, marital status or race). On the other hand, quantitative variables offer information relative to a measurable quantity of magnitude, such as meters of a certain length or grams of a certain weight.

Once both the objectives of the statistical study, and the variables to be analysed have been defined, the next step is to obtain the information. This information may come from primary sources (that the research team obtains directly from the population under study) or from secondary sources (information available from accredited organizations that offer complete confidence to the researcher in the procedure for collecting the information as in the methodology used to process the data).

For data collection, and especially in the field of social sciences where it is frequent the use of surveys or personal interviews as research instruments, the development of the instrument and the choice of the sampling system have a central importance, since the availability of the information, that will later be analysed, depends on them. Among common problems encountered during this phase of a research we have the absence of relevant information, the confusion in the respondents' answers, the induction of bias in the answers or the low participation and disinterest of the interviewees.

It is advisable to carry out a pilot study prior to the final to evaluate elements such as the consistency shown in the responses by the interviewees; the reliability of the answers, ensuring that questions measure what they are intended to, the interviewees' degree of exhaustion according to the extension of the questionnaire, as well as the degree of complexity of the instrument, among others. All this must be evaluated simultaneously by specialists from different disciplines that converge on the topic for which the instrument has been prepared and in which the statistical study is framed.

Descriptive analysis is the study of the data that allows the description, summarization and graphic representation of the information obtained from a sample. It is usually carried out within the first phase of a statistical study and its objective is to describe the main characteristics of the individuals subject of study and the variables measured, as well as finding patterns, analysing the existence of relationship or differences between variables or groups of them and determining the existence of missing values or outliers that may have been included during the data tabulation process.

It consists of three elements that do not necessarily have to appear simultaneously in the analysis: frequency tables, graphical representations and descriptive measures. The implementation of each one

of these elements may vary depending on the nature of the analysed variable, so that the configuration and way of elaborating tables differs if the variable is qualitative or quantitative, or even if the number of modalities is high. Likewise, the use of some graphics such as a box-plot diagram or histogram makes no sense if the variable being analysed is qualitative. Neither do, as mentioned above, descriptive measures.

Frequency tables represent the distribution of a set of values according to the categories or modalities of the variable. They are used to summarize the information or to study possible relationships between two variables – this is the case of contingency tables or cross tables. In the case of qualitative or quantitative variables with a discrete and reduced set of values, they are usually developed discretely for each modality. If, on the other hand, the variable has a large number of different values, it is recommendable to combine them by creating intervals. Graphical representations have similar utilities and also allow a visual analysis of the information.

There are many descriptive measures that allow to obtain information about the data. Univariate analysis can be classified into measures of central tendency such as mean, median and mode, dispersion measures such as variance, standard deviation, range and quintiles, and shape parameters like the ones analysing the asymmetry or kurtosis of the distribution. The objective of bivariate analysis is that of determining the relationship between variables – Pearson correlation coefficient and the Spearman correlation coefficient are examples of this.

Parametric and Nonparametric Tests

Hypothesis testing is the procedure in which it is determined, based on sample statistics, whether it is acceptable (having previously set a degree of uncertainty) that a property is true for the population from which such sample came, or not. Therefore, the objective of this technique is to decide if it is possible to infer a characteristic that was noted in the sample to the whole population. In order to do this, it is necessary to establish the population previously and in an exhaustive way – also, the sample used to perform the contrast has to be randomly selected.

Parametric and nonparametric tests are based on the calculation of a sampling measure denominated test statistic, whose distribution is known so that it is possible to evaluate the probability that such statistic takes the value that has been obtained in the test if the hypothesis is true. A high probability would lead to prove the hypothesis tested. This distribution is known by the researcher, as the necessary conditions for the application of this technique guarantee it – thus ensuring the correct probability of acceptance of the hypothesis tested.

When testing a hypothesis, it is necessary to acknowledge the existence of two possibilities of error during the process: that of refuting the hypothesis tested even though it is true (previously determined probability called “significance level”) and that of accepting the hypothesis even though it is false. The probability of not committing such mistake is called “power” and it decreases when the significance level does. Two types of hypothesis test can be distinguished: parametric test and nonparametric test. The former has a higher power, which means that for given significance level, the probability of correctly accepting the hypothesis is greater. However, its implementation is more restrictive.

There are a lot of types of hypothesis test in the different fields of Statistics, most of them integrated in more complex techniques, for which their application is integrated within them. Some of the hypothesis tests most used in research articles are shown in Table 1, where it is indicated the hypothesis that is contrasted as well as the variable types for which these tests are adequate. It is necessary to emphasize that the grouping of values into categories can reduce the values of the given variable, resulting in a

lower level of measurement regarding its treatment, that is, a quantitative variable, once grouped, would be treated as qualitative ordinal, or an ordinal qualitative as qualitative nominal.

Table 1. Parametric and nonparametric hypothesis tests most used in research

Goal	Type of variable		
	Cuantitative (with normality)	Ordinal	Nominal
Normality test	Kolmogorov- Smirnov test Shapiro-Wilks test		
Compare 1 group with a theoretical value	Mean test: One sample t test	Rank test, Wilcoxon's test	Chi -Square test
Compare 2 unpaired groups	Compare means: Independent samples t test	Mann-Whitney's test	Fisher's test
Compare 2 paired groups	Compare means: Paired samples t test	Wilcoxon's test	McNemar's test
Compare k unmatched groups	Compare means: One-way ANOVA	Kruskall-Wallis test	Chi -Square test
Compare k matched groups	Compare means: Repeated measures ANOVA	Friedman's test	Cochrane's test
Quantify association between k groups	Pearson's correlation	Spearman's correlation	Contingency tables and coefficients

Principal Component Analysis and Factor Analysis

These types of analysis are framed within multivariate techniques, whose objective is to reduce the dimensionality of a data set containing a high number of variables to a smaller set of variables, uncorrelated and constructed from linear combinations. These new variables are called “components” or “factors” and they are obtained in decreasing order of importance depending on the explanatory capacity of the data. These techniques are based on the fact that, if a set of variables is strongly related, the dimensionality of such set is smaller than the number of variables on it.

The main difference between principal component analysis (PCA) and factor analysis (FA) is that, while the first analyses the total variance of the variables, FA evaluates the common variance of the variables (or covariance), so factor construction is made by maximizing the common variance and not the total variance. In addition, in PCA the components are constructed as a linear combination of original variables while the variables are explained, also as a linear combination, by factors. FA can be used to confirm which constructs underlie a set of variables - for example, in a questionnaire.

There are different procedures in order to construct components or factors. However, in all of them, minimizing dimensionality means losing explanatory capacity. Due to the organization made in the extraction process of these, such loss will be lower within the last ones, so those will be discarded. The number of components or factors selected will depend on the desired proportion of variance explained by those.

These techniques are suitable as long as the variables under study are numerical, without having to assume that they follow any concrete probability distribution. However, when the data set is distributed as a multivariate normal distribution (which is, in practice, extremely restrictive), both the analysis and the interpretation of components and factors can be done deeper. On the other hand, it is necessary that the sample size is significantly bigger than the number of variables and, obviously, a high correlation

between variables is needed. Otherwise, dimensionality reduction would be impossible and the application of these techniques would be meaningless. More information can be found in Bryant and Yarnold (1995).

An example of the application of the principal component analysis (PCA) is set forth: given a large set of socio-economic indicators of different kinds, corresponding to different countries of the world, such as the school enrolment ratio, infant mortality rate, gross domestic product (GDP), energy consumption per capita, or the annual rate of deforestation. The PCA allows us to estimate a set of variables, such as a linear combination of some of the previous ones, that can explain more complex factors and processes such as development or sustainability indexes for the different countries involved in the study, reducing that way the dimensionality of the data set.

A large part of the applications of exploratory factor analysis (FA) is carried out in the analysis of complex cognitive processes in the fields of psychology and sociology. Some characteristics such as individuals' attitudes or beliefs are concepts that cannot be directly asked in a questionnaire due to its complexity. For this reason, the researcher performs a decomposition of these characteristics into simpler components (called factors) and elaborates, for each of them, a set of items that allow them to be measured. The exploratory factor analysis allows us to test the suitability of the instrument created by the researcher for the measurement of that complex characteristic and its corresponding factors.

Causal Models

Sometimes, two types of variables can be distinguished: exogenous variables, whose values are determined by factors or variables external to the data set, and endogenous variables, which can be explained through other variables of the set. A causal model is any mathematical model that allows estimating the value of one or more endogenous variables from known values from the exogenous values. Sometimes, endogenous variables can, in turn, act as exogenous predictors of others. Therefore, the objective of this group of techniques is to estimate, with as little mistakes as possible, the values of a variable from known values of other variables, which are the cause of the first. This allow us to estimate, for instance, the probability that an individual will develop a disease based on medical tests taken or the growth of the GDP of a country before the year has finished. The ultimate aim is that of obtaining useful information that allows decision-making.

There are different types of causal models depending on the quantitative or qualitative nature of the variables. The most used ones are: regression analysis (in particular, linear regression, in which most of the variables are quantitative), logistic model, in which the dependent variable is dichotomous and in which the probability of occurrence of the event determine by it is calculated; and variance analysis, in which the endogenous variable is quantitative and the exogenous variables are nominal qualitative variables. The objective of variance analysis is that of determining how the measure of the dependent variable changes depending on the function of the different modalities of factors. Considering the simplest case, these models coincides with multiple median test.

In the case of linear regressions, the necessary assumptions for the application of these models, in addition to those considered about variable's nature, are: normality, homoscedasticity and absence of correlated errors, as well as absence of collinearity between explanatory variables. A refuted hypothesis can be rectified by the application of correction methods. The necessary conditions for the application of logistic regression are less restrictive in practice: absence of collinearity between exogenous variables, independence of errors, absence of outliers and a big enough sample. Variance analysis requires normality of endogenous variables. However, the absence of this condition can be replaced, for a factor, by applying the Kruskal-Wallis test.

Causal models are often used in all fields of science and, particularly, in the field of social sciences. Due to the main objective of these models, which is to predict the value of one or more system variables from the values taken from other variables, rather than estimating the causal model itself, non-parametric methodologies are currently proliferating focusing exclusively on the improvement of the estimation of the endogenous variable value. These methodologies use the data as the main source and are characterized by autonomous learning and by an internal function called *black box*. These techniques are included in the field of artificial intelligence.

Structural Equation Models

Structural equation models share common characteristics with factor analysis and causal models, previously analysed. Besides the variables that can be observed through data collection, we are also provided with others, called “factors” or “latent variables”, which cannot be directly measured – consequently, it has to be done through the latter as their values are absent. This technique allows to construct causal models between measurable variables and latent variables, as well as constructing causal relationship between hidden variables. In other words, this can be understood as the application of several factor analysis in which factor relationships are allowed and can also be calculated. It is usually used for the verification of causal models provided by the theory.

Therefore, the main advantage of the structural equation models (SEM) with respect to the before mentioned techniques that use the combination (PCA, FA) is that SEM allow the definition of complex systems in which different types of relationships can be proposed and estimated. These relationships are expected to be found among variables of a different nature existing in the system (both latent and observable variables). This allows to contrast theoretical relationships from empirical data. For this reason, SEM models are called confirmatory models.

The starting point in the estimation of a structural equation model is the theoretical model that the researcher wishes to contrast. From this, the researcher designs a path diagram that includes both the variables and the relationships that are part of it. From this diagram, the experimental model to be estimated can be designed, which will allow confirming the theoretical model of origin. It is at this point that the researcher must gather all the information required for the estimation of the model and, after confirming the verification of the basic assumptions required, apply the theoretical model to the data, obtaining as a result the confirmation or not of the theoretical model applied.

In order to apply a structural equation model, it is necessary to make a great number of observations, as the number of parameters that have to be estimated is, in general, very high. Moreover, a strong correlation between variables can add ad noise and damage the estimation. Multivariate normal distribution of the data is necessary for the successful implementation of this technique. This is because, in that case, it would be possible to apply a maximum likelihood method for parameters estimation. However, this hypothesis can be eased as long as the variables are symmetric and mesokurtic – in this case, other estimation methods could be applied.

STATISTICAL SOFTWARE

Descriptive Analysis

It is possible to create tables, graphics and descriptive measures by using any statistical software, spreadsheet or even by using a scientific calculator. Also, it is possible to do so by using the R software, and without the need of installing additional packages other than those by default. Commands are generally intuitive and can be consulted in any basic R manual or in James, Witten, Hastie and Tibshirani (2013).

Parametric and Non-Parametric Tests

Statistical software such as STATA or SPSS allow the execution of many of them. In most cases, the execution of a single instruction in R is sufficient in order to obtain results. Functions such as *t.test()*, *var.test()* or *prop.test()* are integrated into the basic package and allow the realization of hypothesis tests for the value of the mean, variance or proportion of a population, as well as the comparison between two populations. For more information, see James, Witten, Hastie and Tibshirani (2013).

Principal Component Analysis and Factor Analysis

There are different libraries in R that allow principal component analysis. One of them is *ade4* (Chessel, Dufour & Thioulouse, 2004). From a previously defined data table, it is only necessary to execute the function *dudi.pca()* from the library to create an object containing the analysis. Functions *inertia.dudi()*, *s.corcicle()* and *s.label()*, applied to the created object, can return, in addition, contributions of each components and two types of graphic representations, respectively.

On the other hand, in order to perform a factor analysis with R we can use the library *stats* of R Core Team (2017), which includes the function *factanal()*, with which it is possible to perform a complete factor analysis, or *loadings()*, to determine factor weight of each variable.

Causal Models

The application of causal models with R is reduced to the execution of a single command. The function *lm()* can be used to estimate linear regression models, whereas for other non-linear models, the function would be *aov()*, which includes logistic regression models, *glm()*, and variance analysis models. All of them are included in the library *stats*.

Structural Equation Models

There is specific software to calculate structural equation models such as Lisrel or AMOS, which uses the driving force of the software SPSS. We can also find libraries in R, such as *lavaan*, by Rosseel, Y. (2012), with the function *sem()*; as well as for flow chart representation, like the package *lavaanPlot* by Lishinski, A. (2018).

CONCLUSION

Data analysis is a tool that allows to obtain a large amount of information from a set of variables observed on a population, with which to optimize the context in which decision-making has to be made. However, its application must be carried out with great rigor, since the refutation of a hypothesis of the mathematical theories underlying the statistical tool could lead to wrong or pointless conclusions. Because of that it is crucial that the researcher has full control of the conditions under which the technique is applicable, as well as full knowledge of the objectives for which it was designed and the methodology that has to be followed.

In this chapter we have dealt, in a very brief and informative way, with some of the most used data analysis techniques in the field of research, such as: descriptive analysis, parametric and nonparametric hypothesis test, principal component analysis, factor analysis, causal models and structural equation models. The objective is that the reader can conceptually know them and quickly identify the necessary requirements for their application, as well as the objectives for which these techniques are applied.

FUTURE RESEARCH DIRECTIONS

The significant incidence that the refutation of the necessary hypothesis has on the results motivates the extension of this work in three directions. Firstly, it is possible to quantify, by means of a simulation, the degree of affectation that the refutation of each hypothesis has on the conclusions obtained after the application of each technique. Secondly, it would be of great interest to carry out a review of the literature in order to analyse the rate of existing research in which there is a breach of the *a priori* hypothesis, grouping them by technique or field of research. Finally, there is a great number of techniques that could not be defined in this chapter due to lack of space and that could be combined in order to complete the list presented here.

KEY TERMS AND DEFINITIONS

Causal Models: Mathematical functions that allow estimating the value or one or more variables, called “endogenous variables”, from known values of other variables that have a significant influence on the former and that are called “exogenous variables”. Its construction is done by minimizing the error made during the estimation.

Data Analysis: It is a set of techniques that allow us to examine a data set with the aim of obtaining a set of conclusions that can facilitate later decision-making.

Factor Analysis: Multivariate data analysis technique that allows to reduce the dimensionality of a high set of interrelated variables through a set of variables called “factors”, from which the original variables can be extracted by means of linear combinations of them. Their construction is done by maximizing the common variance of the variables.

Principal Component Analysis: Multivariate data analysis technique that allows to reduce the dimensionality of a high set of interrelated variables through linear combinations ordered from greater to lesser explanatory capacity of the total variance of the set, and independent of each other.

Statistical Inference: It is a set of techniques of data analysis that, together with probability calculus, allow to induce the behaviour of a population from the information provided by a sample of it.

Structural Equation Models: Confirmatory technique of data analysis that allows to demonstrate an estimate effects and causal relationships between multiple variables, hidden or observable, through a family of multivariate models.

Panel Data: A Case Study Analysis

INTRODUCTION

In Statistical Data Analysis, when analyzing a dataset containing variables observed through time, Panel Data regression analysis methods are commonly used. Panel data research, also associated with longitudinal or cross-sectional time-series data ($t=1, \dots, T$), can be used in the study of varied types of entities, from companies or countries to individuals ($i=1, \dots, N$). From the perspective of data structure, spatial panel data models are the combination of conventional cross-sectional and time series data models, as represented by (Zhou & Yamaguchi, 2018):

Figure 1. Structure of panel data models

(a) Spatial panel data models			
i	t	y	x
1	1	$y_{1,1}$	$x_{1,1}$
1	2	$y_{1,2}$	$x_{1,2}$
1	3	$y_{1,3}$	$x_{1,3}$
2	1	$y_{2,1}$	$x_{2,1}$
2	2	$y_{2,2}$	$x_{2,2}$
2	3	$y_{2,3}$	$x_{2,3}$
3	1	$y_{3,1}$	$x_{3,1}$
3	2	$y_{3,2}$	$x_{3,2}$
3	3	$y_{3,3}$	$x_{3,3}$

(b) Cross-sectional data models			
i	t	y	x
1	1	$y_{1,1}$	$x_{1,1}$
2	1	$y_{2,1}$	$x_{2,1}$
3	1	$y_{3,1}$	$x_{3,1}$

(c) Time series data models			
i	t	y	x
1	1	$y_{1,1}$	$x_{1,1}$
1	2	$y_{1,2}$	$x_{1,2}$
1	3	$y_{1,3}$	$x_{1,3}$

Panel data research can provide means to control subjacent variables not observed or measured. Thus, it accounts for individual characteristics, for example, when studying the evolution of several communities or groups in social media through time, differences in behaviors across communities or variables that change over time but not across communities (i.e., global rules, agreements between communities or social media platforms rules)

DOI: 10.4018/978-1-7998-3479-3.ch045

This document is focused in two techniques used to analyze panel data:

- Fixed effects
- Random effects

Thus, the authors initiate the research by introducing the reader to the background state of the art regarding Panel Data. Then, the primary focus of the chapter considers the introduction to the case study data and obtained results. Results start with the model calibration for the Linear Regression. Additionally, the authors present and explain the case study results for four specifications, one-way or two-way, fixed or random effects, and compare the final results.

BACKGROUND

Historically, econometric and statistical models have been developed by using cross-sectional or time-series data (Washington, Karlaftis, & Mannering, 2003). However, in several cases, there is an availability of data based on cross-sections of individuals observed over time (or other observational units such as firms, geographic entities, and so on). Data which combines cross-sectional and time-series characteristics, can be called **panel data**, **pooled data** or **longitudinal data** (Dougherty, 2006).

Panel data can provide predictions on the evolution of a certain dependent variable according to other variables that are measured among distinct entities (cross-sectional) and time intervals (time series). Thus, it allows researchers to construct and test realistic behavioral models that cannot be identified using only cross-sectional or time-series data. Formally, a panel data has the following form (Kunst, 2011)

$$X_{it}, i=1, \dots, N, t=1, \dots, T.$$

Panel data can be represented in a rectangular form, like a board. Dimension i is called the “individual dimension,” and t is the time dimension. X can be a scalar (real) variable or also a vector-valued variable. Additionally, a general panel data regression model is written as (Hauser, 2013)

$$y_{it} = \beta_0 + x'_{it}\beta + \epsilon_{it}.$$

where:

x'_{it} is a K dimensional vector of explanatory variables, without a constant term,

β_0 the intercept, is independent of i and T .

β is a $(K \times 1)$ vector, the slopes, is independent of i and T .

ϵ_{it} the error, varies over i and T .

Individual characteristics (which do not vary over time), z_i may be included. In this case, the panel data regression model is written as

$$y_{it} = \beta_0 + x'_{it}\beta_1 + z'_i\beta_2 + \epsilon_{it}.$$

where z'_i is a K dimensional vector of individual characteristics (time-invariant).

Panel data analysis provide many **advantages** over conventional cross-sectional or time-series datasets (Hsiao, 2003). The main advantages are:

- First, from a statistical perspective, panel data usually give the researcher a large number of observations, which increase the degrees of freedom and reduce the collinearity among explanatory variables. Thus, in comparison with time-series data, panel data improves the efficiency of the parameter estimates.
- Second, panel data allows analyzing questions that cannot be adequately addressed using either time-series or cross-sectional data (Washington et al., 2003). In this context, the author gives the following example: “suppose that a cross-section of public transit agencies reveals that, on average, public transit subsidies are associated with 20% of increased ridership. If a homogeneous population of public transit firms is available, this might be construed to imply that a firm’s ridership will increase by 20% given transit subsidies. This might also be the implication for a sample of heterogeneous firms. However, an alternative explanation in a sample of heterogeneous public transit firms is that the subsidies have no effect (0% increase) on four-fifths of the firms, and raise ridership by 100% on one-fifth of the firms. Although these competing hypotheses cannot be tested using a cross-sectional sample (in the absence of a cross-sectional variable that “explains” this difference), it is possible to test between them by identifying the effect of subsidies on a cross-section of time series for the different transit systems.”
- Third, panel data allows researchers to check which specifications are appropriate, from the simplistic to the complex. Additionally, panel data allows accounting for cross-sectional heterogeneity by introducing additional parameters into the model (Washington et al., 2003). This way, testing for cross-sectional homogeneity is equivalent to testing the null hypothesis that these additional parameters are equal to zero.

Notwithstanding the advantages associated with panel data, when compared with cross-sectional or time-series data, panel data models have inherent disadvantages that should be reckoned. Thus, during analysis fails to account the following issues could seriously affect the estimated parameters and lead to inappropriate statistical inferences.

- First, and the most important, is **heterogeneity** bias (Hausman & Taylor, 1981). The cross-sectional units involved in the regression may have substantial differences that are not explicitly revealed by the data, leading to a model with limited or no efficiency. A strategy to account for this heterogeneity is to include additional parameters that can explicitly explain it. If heterogeneity across cross-sectional units is not considered in a statistical model, estimated parameters are biased because they capture part of the heterogeneity. Indeed, as noted by (Greene, 2012), cross-sectional heterogeneity should be the central focus of panel data analysis.
- A second issue is a **correlation in error terms**. Since an entity is repeatedly observed throughout time, it is very likely to exist a correlation between the error terms for those distinct time instants. Despite this, some disturbances associated with observations in one period are dependent on disturbances from prior time periods (Washington et al., 2003). This compromises the efficiency of Ordinary Least Squares (OLS) methods, requiring other approaches such as Generalized Least Squares (GLS).
- A third issue is the presence of heteroscedasticity, which refers to the variance of the disturbances not being constant across observations. OLS methods assume that error terms are independent and

identically distributed (iid). This might not be the case of panel data. Again, the efficiency of OLS can be compromised (Sobral & Dionísio, 2015).

In order to overcome these issues, two types of effects should be considered: **one-way** and **two-way**. One-way effects models consider one set of dummy variables (e.g., country, year), while two-way effects models consider two sets of dummy variables, in which one of them is necessarily a time dimension (e.g., country and year). Those sets are used to evaluate differences in intercept or variance of the error terms. Furthermore, in a one-way model, the error term is provided by $\epsilon_{ij} = \mu_i + v_{ij}$ where μ_i is the unobserved individual specific effect and v_{ij} is a random term. In a two-way model, the error term is given by $\epsilon_{ij} = \mu_i + \lambda t + v_{ij}$ where λt denotes the unobserved time effects in the regression (Sobral & Dionísio, 2015).

When differences are assessed in the intercept, the models are considered to be of fixed effects. However, when differences are evaluated in the variance of the error terms, the models are supposed to be of random effects. The main difference between them relies on the role of the dummy variables. Thus, if dummy variables are considered as a part of the intercept, a fixed effect model should be considered. If dummy variables act as an error term, there is considered a random effect model (Hun Myoung, 2009).

Fixed Effect Models

Fixed effect models examine group differences in intercepts, assuming the same slopes and constant variance across entities or subjects. Since a group effect is time-invariant and considered a part of the intercept, it is allowed to be correlated to other regressors (Nunes & Ferreira, 2013). Testing for the joint significance of the included fixed effects parameters (the dummy variables) is straightforwardly conducted using the Chow F test, which is given by

$$F_0 = \frac{(RRSS - URSS) / (n - 1)}{URSS / (nT - n - P)} \sim F_{n-1, n(T-1)-P}$$

for the one-way model, and is given by

$$F_0 = \frac{(RRSS - URSS) / (n + T - 2)}{URSS / ((n - 1)(T - 1) - P)} \sim F_{n+T-2, (n-1)(T-1)-P}$$

for the two-way model, where:

n is the number of cross-sectional units (individuals, counties, states, etc.),

T is the number of time periods,

P is the number of independent variables (explanatory variables).

where $RRSS$ are the restricted residual sums of squares from OLS (ordinary least squares) on the pooled model and $URSS$ are the unrestricted residual sums of squares from the model with fixed effects included (break in two points).

The null hypothesis for the test is that there is no break point (i.e., the data set can be represented by a single regression line) and, consequently, Ordinary Least Squares regression is favored. The alternative hypothesis is that fixed effects should be considered.

Random Effect Models

Random effect models estimate variance components for groups (or time) and error, assuming the same intercept and slopes. The is part of the errors and thus should not be correlated to any regressor. The difference among groups (or time periods) lies in their variance of the error term, not in their intercepts. An advantage of random effects is that it can include time-invariant variables, like age or gender. In the fixed effects model these variables are absorbed by the intercept.

Random effects are examined by Breusch and Pagan's Lagrange multiplier (LM). The null hypothesis of this test is that there are no group effects in the random effects model (Duarte, Lamounier, & Takamatsu, 2007), i.e., the pooled Ordinary Least Squares regression is favored (Nunes & Ferreira, 2013). However, if the hypothesis is rejected, it means that some effects should be considered.

Fixed Effect vs. Random Effect Models

Hausman test compares fixed effect and random effect models. Thus, computation of the Hausman statistic requires estimates of both the random and fixed effects models.

Hausman statistic has a chi-square distribution with as many degrees of freedom as there are predictors in the model (Worrall, 2010). It allows to see if there is a correlation between the individual errors and the regressors in the model, and the null hypothesis is that there is no correlation between the two (Martins, 2006). In other words, the null hypothesis of Hausman test is that the preferred model is random effects. The alternate hypothesis is that the preferred model is fixed effects.

Systematically, Table 1 presents a summary of the tests used to analyze effects of panel data models.

Table 1. Summary of statistical tests

	Test	H0	H1
Fixed effects	Chow F test	There are no groups effects (OLS regression is indicated)	There are some effects (regression with fixed effects is indicated)
Random effects	Breusch-Pagan Lagrange Multiplier test	There are no groups effects (OLS regression is indicated)	There are some effects (regression with random effects is indicated)
Fixed effects vs. Random effects	Hausman test	The preferred model is random effects	The preferred model is fixed effects

The **goodness-of-fit** of the models was assessed by the R^2 values. R^2 is a statistical measure of how close the data are to the fitted regression line. It is also known as the coefficient of determination, or the coefficient of multiple determination for multiple regression.

The definition of R^2 is fairly straight-forward: it is the percentage of the response variable variation that is explained by a linear model (Stone, Scibilia, Pammer, Steele, & Keller, 2018b). Thus,

$$R^2 = \frac{\text{Explained variation}}{\text{Total variation}}$$

Since R^2 is a percentage, it is always between 0 and 100%, 0% indicates that the model explains none of the variability of the response data around its mean, and 100% indicates that the model explains all the variability of the response data around its mean.

However, R^2 cannot determine whether the coefficient estimates and predictions are biased because every time a predictor is added to a model, the R^2 increases, even if due to chance alone, and it never decreases. Therefore, a model with more terms may appear to have a better fit. Thus, adjusted R^2 is considered to solve this problem, since it is a modified version of R^2 that has been adjusted for the number of predictors in the model. The adjusted R^2 increases only if the new term improves the model more than would be expected by chance, and it decreases when a predictor improves the model by less than expected by chance (Stone, Scibilia, Pammer, Steele, & Keller, 2018a).

FOCUS OF THE ARTICLE

Objective

The objective of this work is to explain and exemplify how to use panel data models based on the R programming language. In this sense, the presented problem is to estimate the number of publications in a set of institutions. Therefore, the aim is to compare prediction capabilities concerning a classical regression model as benchmark. To do this, several lines of code and their output in R language are presented. Also, the most critical values obtained in the output are discussed, as well as the main conclusions are drawn.

Data

The fictitious database used in this study contains records of 246 research institutes (synthetic data), collected over six years (from 2011 to 2016). Thus a total of 1476 instances are available. For each research institution in each year, several variables are considered such as:

- Researchers - represents the average number of researchers
- Supervisors - represents the average number of supervisors
- Publications - represents the total number of publications
- Rcenters - represents the number of research center
- Projects - represents the total number of projects

R software was used to explore the presented analysis. So, the first ten rows of the dataset could be obtained by the expression below.

```
Computer Code      head(Panel, 10)
Output   Institution Year Researchers Supervisors Publications Rcenters Proj-
ects
1         1 2011      12.2         6.0          25          3         3
2         1 2012      15.0         6.0          30          3         3
3         1 2013      14.0         5.0          37          3         5
4         1 2014      14.2         6.0          37          3         5
5         1 2015      14.7         6.0          39          3         5
```

6	1	2016	16.4	5.2	44	3	5
7	2	2011	17.2	7.0	39	3	5
8	2	2012	17.2	8.4	43	3	5
9	2	2013	18.9	8.7	49	3	6
10	2	2014	20.2	8.7	54	3	7

In order to understand the data variation, some simple statistics should be performed, namely, the counting of discrete variables – Institution and Year – and a descriptive analysis of continuous variables (mean, maximum and minimum, median and quartiles) – Researchers, Supervisors, Publications, Rcenters, and Projects.

```
Computer Code      ##counting of Institutions
length(unique(Panel$Institution))

##counting of Years
length(unique(Panel$Year))

## descriptive analysis of Researchers, Supervisors, Publications, Rcenters
and Projects variables
summary(Panel[,3:7])

```

Based on the outputs, it is possible to observe that 246 institutions and six years are effectively presented in the database. Regarding continuous variables, a high variation is observed in most variables. Rcenters is the variable with less variation since it varies from 2 to 5.

As the objective of this study is to find a model to estimate the number of publications, Publications variable will be considered a dependent variable. This variable varies from 6 to 242 with a mean equal to 43.84 and a median equal to 37, which may indicate that the research center with 242 publications could be an outlier of the number of publications.

Researchers, Supervisors, Rcenters, and Projects will be used in the model as independent variables.

Methodology

The present study has a main objective to analyze some models of panel data and verify which is the best to estimate the number of publications. In order to do this, several models were tested using R software. The R code used to make all analysis is only an example. Probably, other packages or other expressions could be used. However, in the present work, in order to estimate panel data regression models, plm package in R was used (Croissant & Millo, 2008).

The first phase consists of the discussion of the influence of the independent variables (IV). To get conclusions about this, the input information was the correlation matrix, and the significance of the coefficients results from the tested models. After narrowing the IV that is significant to the model, the chosen model was tested with the selected variables in order to test for improvements.

Thus, Table 2 presents a summary of the panel data models used in this work, as well as a description of each model to a best understanding. In addition to that model collection, an initial OLS model was built. For instance, if the statistical analysis indicates that there are no relevant fixed or random effects, it is likely that a regular OLS model will suffice for the estimation.

Table 2. Panel data models

Model		Description
1	OLS	Considers only the variables, create a regular linear regression with no group effects
2	Fixed effects – one-way error (by institution)	Considers that there are fixed effects only in one dimension and creates the model by grouping by institution
3	Fixed effects – one-way error (by year)	As model 2, considers fixed effects in one dimension, but groups by year.
4	Fixed effects – two-way error	Add both dimensions, grouping by farm and year.
5	Random effects – one-way error (by institution)	The same as model 2, but resorts to random effects.
6	Random effects – one-way error (by year)	The same grouping of model 3, using random effects.
7	Random effects – two-way error	The same as model 4, also considering random effects.

Results

As mentioned before, in order to analyze the best model to estimate the number of publications, it is important to verify how variables are correlated between them. Thus, the R code and the output of the correlation matrix of the variables in study is presented. The results improve the understanding of how the IV are related to the DV (dependent variable) – Publications – and if the IV are related to each other.

```
Computer Code      library("Hmisc")
```

```
correlation_matrix <- rcorr(as.matrix(Panel[,3:7]))
```

```
correlation_matrix
```

```
Output      Researchers Supervisors Publications Rcenters Projects
Researchers 1.00        0.70        0.95        0.52        0.90
Supervisors 0.70        1.00        0.62        0.32        0.56
Publications 0.95        0.62        1.00        0.50        0.95
```

Rcenters	0.52	0.32	0.50	1.00	0.46
Projects	0.90	0.56	0.95	0.46	1.00

n= 1476

P

	Researchers	Supervisors	Publications	Rcenters	Projects
Researchers	-	0	0	0	0
Supervisors	0	-	0	0	0
Publications	0	0	-	0	0
Rcenters	0	0	0	-	0
Projects	0	0	0	0	-

From that analysis, it is visible that Researcher and Projects have the most substantial influence in the DV ($corr=0.95$, $p<0.0001$). It was also noticeable that Rcenters has a lower correlation with DV ($corr=0.50$, $p<0.0001$). However, the main conclusion obtained from the presented output is that all independent variables are significantly correlated to the dependent variable, which may indicate a good choice of independent variables to define the panel data model regression.

Model 1. OLS

```
Computer Code      library(plm)
inst.fixed.lm = lm(Publications ~ Researchers + Supervisors + Rcenters + Proj-
ects, data = Panel)
summary(inst.fixed.lm)
Output Call:
lm(formula = Publications ~ Researchers + Supervisors + Rcenters +Projects,
data = Panel)
```

	-33.965	-3.294	0.135	3.301	29.982

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	-0.19433	0.85438	-0.227	0.8201
Researchers	1.25933	0.04319	29.155	<2e-16 ***
Supervisors	-0.03108	0.04072	-0.763	0.4455
Rcenters	0.57102	0.34309	1.664	0.0963 .
Projects	3.49239	0.08453	41.315	<2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 6.68 on 1471 degrees of freedom

Multiple R-squared: 0.9532, Adjusted R-squared: 0.9531

F-statistic: 7488 on 4 and 1471 DF, p-value: < 2.2e-16

Results of the OLS model shows the variation of residuals, the coefficients, and some important statistics. First, the $Pr(>|t|)$ is a two-tail p-value that test the hypothesis that each coefficient is equal to 0. Since Researchers and Projects variables presents coefficients with a $Pr(>|t|) < 0.05$, the null hypothesis is rejected. Thus, at a significance level of 5%, Researchers and Projects have coefficients different of zero and contributes to the model (eventually, Rcenters could be considered at a significance level of 10%). Additionally, the difference in the coefficients of Researcher and Projects could indicate that Projects have a higher influence on the DV (higher coefficient value). The value of t also is a good indicator, since the higher the t-value the higher the relevance of the variable.

Second, results of R2 and adjusted R2 are 0.9532 and 0.9531, respectively, which means that approximately 95% of the total variability of Publications is explained by the predictors.

Finally, the output shows the result of a F-test, which test if all coefficients are equal to zero (Torres-reyna, 2010). The model presents an F value of 7488 with 4 and 1471 degrees of freedom, with $p < 0.0001$. The result indicate the null hypothesis should be rejected at a 5% of significance level, indicating that some coefficient is different from zero and, consequently, the model is well defined.

Model 2. Fixed effects – one-way error (by institution)

```
Computer Code      library(plm)
inst.fixed = plm(Publications ~ Researchers + Supervisors + Rcenters + Proj-
ects, data = Panel, index = c("Institution"), model = "within")
summary(inst.fixed)
Output Oneway (individual) effect Within Model
```

Call:

```
plm(formula = Publications ~ Researchers + Supervisors + Rcenters +
    Projects, data = Panel, model = "within", index = c("Institution"))
```

Balanced Panel: n=246, T=6, N=1476

Residuals:

	Min.	1st Qu.	Median	3rd Qu.	Max.
	-27.0000	-1.7500	0.0291	1.8000	21.5000

Coefficients:

	Estimate	Std. Error	t-value	Pr(> t)
Researchers	1.429442	0.059285	24.1112	<2e-16 ***
Supervisors	0.067189	0.057303	1.1725	0.2412
Rcenters	0.449300	0.456434	0.9844	0.3251
Projects	3.067028	0.089962	34.0924	<2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Total Sum of Squares: 168010

Residual Sum of Squares: 21945

R-Squared: 0.86938

Adj. R-Squared: 0.72213

F-statistic: 2040 on 4 and 1226 DF, p-value: < 2.22e-16

The second model (fixed effects, one-way error by institution) shows that only Researchers and Projects have a significant coefficient value. Similar to the first model, Projects have the highest coefficient value and t-value, which could indicate that Projects have a higher influence on the number of Publications (the dependent variable).

Values of R² and adjusted R² are 0.86938 and 0.72213, which indicates that approximately 72% of the total variability of Publications is explained by the predictors.

The model presents an F value equal to 2040 with 4 and 1226 degrees of freedom. Since the p-value is lower than 0.0001, the null hypothesis that all coefficients are equal to zero is rejected, and the model is well defined.

Comparing with the first model, this model seems to be worst, because of the values of R² and adjusted R². However, some specific tests will be performed to indicate the most suitable model.

Model 3. Fixed effects – one-way error (by year)

```
Computer Code      year.fixed = plm(Publications ~ Researchers + Supervisors +
Rcenters + Projects, data = Panel, index = c("Year"), model = "within")
summary(year.fixed)
Output Oneway (individual) effect Within Model
```

Call:

```
plm(formula = Publications ~ Researchers + Supervisors + Rcenters +
      Projects, data = Panel, model = "within", index = c("Year"))
```

Balanced Panel: n = 6, T = 246, N = 1476

Residuals:

Min.	1st Qu.	Median	3rd Qu.	Max.
-33.04541	-3.31680	0.15421	3.30897	28.95882

Residual Sum of Squares: 64394

R-Squared: 0.95153

Adj. R-Squared: 0.95124

F-statistic: 7195.36 on 4 and 1466 DF, p-value: < 2.22e-16

Panel Data

The third model presents R^2 and adjusted R^2 very similar, and approximately 95%. Regarding the coefficients of the independent variables, Researchers, Rcenters and Projects have $p < 0.05$, i.e., they contribute significantly to the model. Similar to the previous models, F-test also presents a $p < 0.001 < 0.05$, indicating the model is well defined.

Model 4. Fixed effects – two-way error

```
Computer Code      two.fixed = plm(Publications ~ Researchers + Supervisors +
Rcenters + Projects, data = Panel, index = c("Institution", "Year"), effect =
"twoways", model = "within")
summary(two.fixed)
OutputTwoways effects Within Model
```

Call:

```
plm(formula = Publications ~ Researchers + Supervisors + Rcenters +
    Projects, data = Panel, effect = "twoways", model = "within",
    index = c("Institution", "Year"))
```

Balanced Panel: n = 246, T = 6, N = 1476

Residuals:

Min.	1st Qu.	Median	3rd Qu.	Max.
-24.669304	-1.618241	0.075276	1.678866	20.595028

Coefficients:

	Estimate	Std. Error	t-value	Pr(> t)
Researchers	1.230850	0.058511	21.0363	<2e-16 ***
Supervisors	0.066872	0.054335	1.2307	0.2187
Rcenters	0.295760	0.432503	0.6838	0.4942
Projects	2.853220	0.086980	32.8033	<2e-16 ***

Total Sum of Squares: 94551

Residual Sum of Squares: 19564

R-Squared: 0.79309

Adj. R-Squared: 0.75004

F-statistic: 1170 on 4 and 1221 DF, p-value: < 2.22e-16

The fourth model analyses the two-way error with fixed effects and presents an R^2 and adjusted R^2 of 0.79309 and 0.75004 respectively. Coefficients of variables Researchers and Projects are those that contribute significantly to the model. Additionally, the F-test indicates that, similarly to the other models, this one is also well defined.

Model 5. Random effects – one-way error (by institution)

```
Computer Code      inst.random = plm(Publications ~ Researchers + Supervisors +
Rcenters + Projects, data = Panel, index = c("Institution"), model = "random")
summary(inst.random)
```

```

Total Sum of Squares: 291830

Residual Sum of Squares: 26450

R-Squared: 0.90936

Adj. R-Squared: 0.90912

F-statistic: 3689.65 on 4 and 1471 DF, p-value: < 2.22e-16

Similar to the previous models, the random effects model (one-way error by institution) output gives some descriptive statistics and the result of some statistical tests. The main results to take into account are the p-value of the coefficients, which indicates variables that contribute to the model. In this case, only Researchers and Projects should be considered. R2 and adjusted R2 indicates a good value of goodness-of-fit, and the p-value of the F-test indicate the model is well defined.

Panel Data

Model 6. Random effects – one-way error (by year)

```
Computer Code      year.random = plm(Publications ~ Researchers + Supervisors +
Rcenters + Projects, data = Panel, index = c("Year"), model = "random")
summary(year.random)
```

```
OutputOneway (individual) effect Random Effect Model

Total Sum of Squares: 1402100

Residual Sum of Squares: 65632

R-Squared: 0.95319

Adj. R-Squared: 0.95306

F-statistic: 7488.37 on 4 and 1471 DF, p-value: < 2.22e-16

The sixth model presents an R² and adjusted R² of 0.95319 and 0.95319 indicating that approximately 95% of the total variability of Publications is explained by the predictors.

Once again, the model is well defined (p-value of the F-test lower than 0.0001 < 0.05). Coefficients of variables Researchers and projects contribute significantly to the model. In particular, Rcenters variable could also be included in the model if the level of significance considered was 10%.

Model 7. Random effects – two-way error

```
Computer Code      two.random = plm(Publications ~ Researchers + Supervisors +

Residual Sum of Squares: 25983

R-Squared: 0.90682

Adj. R-Squared: 0.90657

F-statistic: 3578.94 on 4 and 1471 DF, p-value: < 2.22e-16

The last model presents an R² and adjusted R² of 0.90682 and 0.90657 respectively. The model is well defined since the p-value of the F-test is lower than 0.05, and the variables that should be considered in the model are Researchers and Projects.

Statistical Tests

In order to test the best models, some statistical test may be performed. As described in the previous section, three tests need to be used:

Chow F-test - to evaluate the significance of fixed effects (alternative hypothesis)

```
Computer Code      pFtest(inst.fixed, inst.fixed.lm)
pFtest(year.fixed, inst.fixed.lm)
pFtest(two.fixed, inst.fixed.lm)
Output            F test for individual effects

data:  Publications ~ Researchers + Supervisors + Rcenters + Projects
F = 9.9618, df1 = 245, df2 = 1226, p-value < 2.2e-16
alternative hypothesis: significant effects
```

F test for individual effects

```
data:  Publications ~ Researchers + Supervisors + Rcenters + Projects
F = 5.6365, df1 = 5, df2 = 1466, p-value = 3.734e-05
alternative hypothesis: significant effects
```

F test for twoways effects

```
data:  Publications ~ Researchers + Supervisors + Rcenters + Projects
F = 11.5, df1 = 250, df2 = 1221, p-value < 2.2e-16
alternative hypothesis: significant effects
```

Previous output shows that all p-values of the F-test are lower than 0.05, which leads to conclude that the null hypothesis that there are no break point, i.e., the OLS model is the best, is rejected. The alternative hypothesis is that fixed effects should be considered. This is the conclusion of these tests.

Breusch-Pagan Lagrange Multiplier test - to evaluate the significance of random effects (alternative hypothesis)

```

Computer Code      plmtest(inst.random, type=c("bp"))
plmtest(year.random, type=c("bp"))
plmtest(two.random, type=c("bp"))
Output            Lagrange Multiplier Test - (Breusch-Pagan) for balanced panels

data:  Publications ~ Researchers + Supervisors + Rcenters + Projects
chisq = 1286, df = 1, p-value < 2.2e-16
alternative hypothesis: significant effects

```

```

Lagrange Multiplier Test - (Breusch-Pagan) for balanced panels

data:  Publications ~ Researchers + Supervisors + Rcenters + Projects
chisq = 33.048, df = 1, p-value = 8.992e-09
alternative hypothesis: significant effects

```

```

Lagrange Multiplier Test - (Breusch-Pagan) for balanced panels

data:  Publications ~ Researchers + Supervisors + Rcenters + Projects
chisq = 1286, df = 1, p-value < 2.2e-16
alternative hypothesis: significant effects

```

Regarding the Breusch-Pagan Lagrange Multiplier test, all of them gives p-value < 0.05 which leads to rejecting the null hypothesis, i.e., the preference for the OLS. Thus, these tests allow deciding to consider some effects. Now, it is important to decide between fixed effects or random effects.

- **Hausman test** - in case the null hypothesis is rejected in both previous tests, the test will point the recommended direction towards the best model specification, which is used to assess whether there is a correlation between the unobserved effects and the regressors. If there is, a fixed effects model will be preferred.

```

Computer Code      phtest(inst.fixed, inst.random)
phtest(year.fixed, year.random)
phtest(two.fixed, two.random)
Output            Hausman Test

data:  Publications ~ Researchers + Supervisors + Rcenters + Projects
chisq = 10.935, df = 4, p-value = 0.02731
alternative hypothesis: one model is inconsistent

```

Panel Data

Hausman Test

```
data: Publications ~ Researchers + Supervisors + Rcenters + Projects
chisq = 34.936, df = 4, p-value = 4.788e-07
alternative hypothesis: one model is inconsistent
```

Hausman Test

```
data: Publications ~ Researchers + Supervisors + Rcenters + Projects
chisq = 178.96, df = 4, p-value < 2.2e-16
alternative hypothesis: one model is inconsistent
```

All tests give a p-value lower than 0.05. Similar to previous tests, the null hypothesis is rejected. Thus, the preference for fixed effects instead of random effects should be considered.

Summary of the Models

Table 3 presents a summary of the main values obtained in the analysis performed in the present study. Based on this table, some conclusions should be defined.

Table 3. Summary of panel data models tested

	OLS	One-way (institution)	One-way (Year)	Two-way	One-way (institution)	One-way (Year)	Two-way
Fixed effects							
Constant	-0.19433	-	-	-	-0.919175	-0.194328	-0.960335
Researchers	1.25933***	1.429442***	1.273612***	1.230850***	1.369133***	1.259329***	1.372851***
Supervisors	-0.03108	0.067189	-0.026765	0.066872	0.015672	-0.031075	0.018847
Rcenters	0.57102	0.449300	0.706666*	0.295760	0.484708	0.571023	0.479157
Projects	3.49239***	3.067028***	3.405167***	2.853220***	3.185626***	3.492393***	3.176388***
Statistics							
R²	0.9532	0.86938	0.95153	0.79309	0.90936	0.95319	0.90682
Adjusted R²	0.9531	0.72213	0.95124	0.75004	0.90912	0.95306	0.90657
F (p-value)	-	9.9618 (<0.0001)	5.6365 (<0.0001)	11.5 (<0.0001)	-	-	-
LM (p-value)	-	-	-	-	1286 (<0.0001)	33.048 (<0.0001)	1286 (<0.0001)
H (p-value)	-	-	-	-	10.935 (0.02731)	34.936 (<0.0001)	178.96 (<0.0001)

As described before, fixed effects should be considered as the best option to the estimate publications. Looking at R^2 and adjusted R^2 values it is possible to decide that one-way error (by year) with fixed effects should be considered as the best model to estimate the number of publications.

SOLUTIONS AND RECOMMENDATIONS

As a recommendation in dealing with the consequent lack of knowledge of R language for statistical data analysis, the reader might want to read the throughout R language application to statistics in (Sarmiento & Costa, 2017).

FUTURE RESEARCH DIRECTIONS

As future research direction, it can be useful for the researcher to explore other R packages available in CRAN repository, with the purpose to explore and analyze Panel Data.

CONCLUSION

Following the state of the art introduction, a throughout research template for Panel Data is written in this chapter. With the proposal of an example case study, the reader will hopefully appreciate the advantages within the use of Panel Data to explore his/her datasets with temporal characteristics.

The authors presented a step by step approach to Panel Data, giving extreme importance to tasks like testing fixed or random effects, either individually for each variable or by using a two-way approach.

ACKNOWLEDGMENT

Vera Costa gratefully acknowledges funding from FCT (Portuguese Foundation for Science and Technology) through a Ph.D. grant (Ref. PD/BD/128065/2016). Rui Portocarrero Sarmiento also gratefully acknowledges funding from FCT (Portuguese Foundation for Science and Technology) through a Ph.D. grant (SFRH/BD/119108/2016). The authors want to thank also to the reviewers, for the constructive reviews provided in the development of this publication.

KEY TERMS AND DEFINITIONS

Fixed Effects: Variables that are constant across individuals, i.e., do not change, or change at a constant rate over time (for example, age, sex, or ethnicity).

OLS Regression: Commonly called linear regression. OLS method corresponds to minimizing the sum of square differences between the observed and predicted values.

One-Way Error Model: A model that considers only one group of the data (for example, year or country).

Panel Data: Data derived from a small number of observations over time on a large number of cross-sectional units (for Example, individuals, households, firms, or governments).

Random Effects: Variables that are random and unpredictable (for example, cost of a new car varies when purchased in different years).

Two-Way Error Model: A model that considers two group of the data (for example, year and country).

Applications of Decision Support Systems in Aviation

INTRODUCTION

The air transport industry plays a major role in world economic activity and to maintain the safe and efficient operation of aviation enterprises that allows maximum use to be made of enhanced capabilities provided by technical advances. Nowadays the International Civil Aviation Organization (ICAO) has added in its documents new approaches for achieving the main goals of the organization, which are: to enhancing the effectiveness of global aviation security and to improve the practical and sustainable implementation of preventive aviation security measures. These new approaches include the development of progressive technology and human capability, the improvement of technological resources to improve the quality of decision making of aviation personal (pilots of manned and unmanned aircraft, air traffic controllers, engineers, etc. (ICAO, 2017; ICAO, 2018). The quality of decision dependences is using innovative technology in aviation such as Artificial Intelligence (AI). The AI document “White paper” of IATA (International Air Transport Association) presents the results of IATA research and development activities on AI in collaboration with airlines. The new technologies of AI can be clustered in the following capabilities, such as Machine learning (ML), Natural Language Processing (NLP), Expert Systems, Vision, Speech, Planning, Robotics (IATA, 2016; ICAO, 2018). To increase the productivity of work at each stage of the life cycle (LC) of aviation systems, different AI technologies and methods can be effectively applied (Figure 1).

Figure 1. The synergetic effect - LC of aviation technique with using AI capability

DOI: 10.4018/978-1-7998-3479-3.ch046

Artificial Intelligence is the simulation of human intelligence processes by modeling, computer systems, and machines. These processes include learning (the acquisition of information and rules for using the information); reasoning, estimation, and modeling (using rules to reach conclusions (approximate or definite results)); self-correction (estimation of obtained models). Particular applications of AI include Expert System (ES); Decision Support System (DSS); Automated systems; systems of pattern recognition, speech recognition, and machine vision, etc. (ICAO, 2017; IATA, 2016). AI (and DSS) are effective for minimization risks and improve the quality of decisions in the aviation system.

BACKGROUND

Support for the safe functioning of ANS is one of the most important scientific and technical problems. Statistical data show that human errors account for up to 80% of all aviation accidents (ICAO, 2004). According to ICAO data (ICAO, 2013), compared with 2011, in 2012 the number of incidents in the world decreased by 21%, in 2013 – on 13%; the number of fatalities in 2012 decreased by 10%, in 2013 – on 55%. Consequently, the least number of deaths has been fixed in 2012-2013, starting from 2004. As a result of the decreased number of incidents, an increased number of departures, the frequency of incidents in the world in 2012 has been reduced to 3,2 events per million departures and in 2013 – to 2,8 events per million departures. This is the lowest value since the ICAO started to monitor the frequency of incidents in the world. Aviation systems cannot be wholly free from dangerous factors and connected with them risks, while, the elimination of aviation events and serious incidents continues to be the final goal of human activity in the sphere of aviation safety. Neither human activity nor systems created by it guarantee a total absence of operating errors and their consequences (ICAO, 2013). In such a way, safety is a dynamic characteristic of aviation with the help of which risk factors for flight safety should steadily decrease. It is important to note that the adoption of efficiency indices of ensuring flight safety is frequently influenced by internal and international standards and also by cultural features (ICAO, 2009). While risk factors for flight safety and operating errors are under control, such an opened and dynamic system as civil aviation may be controlled providing the necessary balance between flight performance and safety requirements.

Latest demands of international aviation organizations directed on the implementation of an integrated approach for the improvement of aviation safety. Many ICAO documents describe the problems in aviation and include recommend the creation of support for a solution in each professional situation (ICAO, 2005a; 2005b; 2009). One of the ways to increase safety by timely is the support of pilots in emergency situations (ICAO, 2012). A modern approach, founded on the characteristics (Performance-Based Approach – PBA) (ICAO, 2009), based on the next three principles:

- a strong focus on desired/required results;
- informed decision making (DM) driven by those desired/required results;
- reliance on facts and data for DM.

Herein the principle “using facts and data while DM” admits that tasks shall comply with the widely known in Western management criteria **SMART**, which correspond to the abbreviation of five English words: Specific, Measurable, Achievable, Relevant, Time-bound.

So-called aeronautical DM is DM in a unique environment – aviation. It is a systematic approach to the mental process used by pilots to consistently determine the best course of action in response to a

given set of circumstances. It is what a pilot intends to do, on the basis of the latest information he has (Federal Aviation Administration [FAA], 2008). So, ICAO constantly develops and improves proactive, based on the risks evaluation, methods, directed on the farther decrease in a number of aviation events in the world. Also, ICAO encourages aviation communities to recognize the importance of adherence to the single global approach for safety improvement and monitoring (ICAO, 2013). Manual of ICAO “Global Air Traffic Management Operational Concept” (ICAO, 2005b) presents basic methods and benefits of the support of aviation operators in their professional operations for using DSS for difficult or emergency situations. Documents of ICAO have presented concepts about the Flight & Flow Information for a Collaborative Environment (FF-ICE), including support for a Performance-Based Approach (PBA), Collaborative Decision Making (CDM), System-Wide Information Sharing and Management (SWIM) by trajectory (ICAO, 2017; ICAO, 2018). To ensure effective CDM, it is necessary to create a DSS’s for the operators of the aviation system as a whole.

Expected benefits of this approach such as: from an *airspace user* (pilots), safety systems will be perspective, greater equity in airspace access, greater access to timely and meaningful information for decision support, and more autonomy in DM, including conflict management, will provide the opportunity to better deliver business and individual outcomes within an appropriate safety framework; from a *service provider* (ATM), safety systems will be perspective, including that of aerodrome operators, the ability to operate within an information-rich environment, with real-time data, as well as system trend and predictive data, fused with a range of automated decision-support or DM tools, will enable optimization of services to airspace users; from a *regulatory perspective*, safety systems will be robust and open, allowing safety not only to be more easily measured and monitored, but also compared and integrated on a global basis, not for its own sake, but as a platform for continuous improvement.

Maximum effectiveness and efficiency of actions can be obtained by activities undertaken in the early phases of any system’s life cycle since correcting problems during requirements definition and design is generally the most effective. Figure 2 depicts this process for the ATM system as a whole. It describes how, starting from the conceptual level and even during operation, different players and disciplines make decisions against different criteria – including *safety*. These decisions will progressively define the ATM system (i.e. the way in which it is organized and the way in which people, procedures, technologies and information interact to perform a task) for using different DSS on all stages of operating ATM system.

Figure 2. System safety approach (ICAO, 2009)

A lot of research is being done for improving the work of DSSs. The problems of DSS's informational provision have been considered in the works of scientists (Tarasov, & Gerasimov, 2007; Gerasimov, & Lokazyuk, 2007; Sirodza, 2002). So, DSS may be defined as “an interactive computer system intended to support different types of activity during the decision making including poorly-structured and unstructured problems” (Tarasov, & Gerasimov, 2007; Gerasimov, & Lokazyuk, 2007).

Decision support systems contain common sets of components. The data related components are made of modules that ingest data, format data, store data, transfer data, and archive data. The algorithm related components utilize diverse methods such as atmospheric models, rule-based algorithms, fuzzy logic algorithms, statistical algorithms, the algorithm of DM under uncertainty and risk, data mining algorithms. Development of the automated systems in aviation is associated with an anthropocentric approach and on the principles of human-oriented automation, required new approaches to solving the problems of the Man-Machine interface (ICAO, 1994). One of the effective means of flight safety improvement is the inclusion of DSS to the automated systems of air traffic control (ATC) operators and pilots (Kharchenko, Shmelova, & Sikirda, 2012; 2016; Shmelova, Sikirda, & Belyaev, 2014), development DSS for flight operators (Kharchenko, Shmelova, & Sikirda, 2012; 2016). Now with the advent of UAVs, new systems are considered such as local DSSs for operators of Remotely Piloted Aircraft Systems (RPAS) (Kharchenko, Shmelova, & Bondarev, 2017).

Nowadays a new approach for flight safety provision is forming in global practice. The ICAO's term “Safety Management System” (SMS) integrates operations and technical systems with the management of financial and human resources to ensure aviation safety or the safety of the public (ICAO, 2009). Building an effective SMS of aviation activity requires integrated research of the environment in which aviation enterprises operate. Much research related to the determination of the influence of factors of internal and external management environment of aviation enterprise on the efficiency of its business. Estimating the level of influence of factors of aviation enterprise's management environment on the efficiency of SMS is a perspective task. The structural analysis of the management environment of aviation enterprise has been carried out for DSS in ANS. And, as follows from the analysis, inhomogeneous factors which influence on the aviation activity have been classified and formalized. Inhomogeneous factors of internal and external management environments of aviation enterprise have been systematically generalized using a set-theoretical approach. The influence of factors of internal and external management environment on the aviation enterprise's aviation activity has been determined (Shmelova, Sikirda, Assaul, & Stasiuk, 2015). The authors present an investigation of the management environment of aviation enterprise in ANS determined the influence of factors of internal and external management environment of aviation enterprise on aviation activity. This is a DSSs for managers in aviation enterprises. Safety management of aviation enterprise is directed on the formation and provision the achieving its goals rationally using present resources (labor, material, financial, informational, etc.). These researches are designed for aviation operators such as pilots of manned and unmanned aircraft, flight despatches, ATC operators, aviation managers, as well for scientists, engineers, air crash investigators, teachers, academicians, researchers, and students seeking current research on the application of DSS in the field of aviation.

DECISION SUPPORT SYSTEMS IN AIR NAVIGATION SYSTEM
